Dr. J. F. SMYTH (Wakefield) spoke on the relation of the *Spirochæta pallida* to the histological changes in dementia paralytica. He said that spirochætes were found in 75 per cent. of the cases; they were found most frequently in cases which ran a stormy course. The number of cases examined was 52. The most that could be hoped for under treatment was an arrest of the damaging process to the cortex.

Dr. JOHN BRANDER (Bexley) discussed general paralysis of the insane as a clinical and pathological entity.

Prof. W. H. MAXWELL TELLING (Leeds University) spoke of the value of psychical research to the physician. He declared he had received great benefit from a study of psychic phenomena, and proceeded to review the present state of knowledge and the tendency in the profession concerning this subject. His own attitude was sympathetic towards such subjects as telepathy.

The concluding item was a demonstration by the PRESIDENT on cases of sense deprivation and the primary importance of the aural centres in the cortex cerebri.

ANNUAL CONGRESS OF THE ROYAL SANITARY INSTITUTE.

PLYMOUTH, JULY 16TH–21ST.

THE inaugural meeting on Monday has alrea been touched upon. During the remainder of t week the work of the Congress was, as usual, divid up among many sections. The following notes d with some of the points of special medical inter which arose in the course of the meetings.

Hygiene in Industry.

Mr. Ramsay MacDonald, in his presidential addr to this Section, compared the worker with a delic scientific instrument; the old fashion of putting h to do a job just as it came was now abandoned everyone who had any common sense. Public hea had the individual as its aim, but the community its medium, and included both self-help and mut aid. The work of bodies such as the Natio Institute of Industrial Psychology, the Medi Research Council, and the Industrial Fatigue Boa was putting industrial hygiene in its proper pl as one of the most vital concerns of our country. were still in the transition stage and did not whc heartedly accept the doctrine that the conduct industry is a national concern. The latest attem by the General Council of the Trade Union Congr to explore the conditions of industrial peace were essential contribution to the practical success recent scientific investigations. In industry strai fatigues, and worries were as poisonous to life as w disease germs. A close and detailed study of use to which the human body is put in industry w needed. Mr. MacDonald gave many convinc illustrations from the experience of Dr. C. S. My of unnecessary fatigue and waste of muscular effort factories, which had been easily remedied witl little study. The temperature and ventilation workshops affected not only physical condition the nerves, as shown by temper, general ease, a happiness. It had been found, also, that men var in their suitability for working with machines runn at different speeds; of two men working side by s at similar machines one might be brought to the ve of nervous breakdown by inability to keep up, wl the other might complain of boredom from slowness of the pace. The hygienist was handicap by the fear of the worker that industrial econo meant intensification of labour for him. The solut of all such problems was of immense importance industry both as regards its economic working and internal harmonies, and this department of resea was essential for moulding our organisation of ind trial and sociological relations into a coöperat concord.

International Preventive Medicine.

Dr. L. Rajchman, Medical Director and Secretary the League of Nations Health Committee, in presidential address to the Preventive Medic Section, outlined the policy and methods which l been evolved by seven years' work on the part leading men of many countries of all continents. referred to the services of epidemiological intellige and public health statistics, of technical publicatio and of permanent liaison work with national sanit administrations; to commissions at work and org isations in progress in many countries; and to inve gations of many problems, including those of sleep sickness in Equatorial Africa, small-pox and encepl itis in Northern Europe, leprosy in South America the East, malaria throughout the world. Ot hopeful enterprises included the practice of p ventive methods by health insurance organisatio the adoption of common standards for sera vaccines, and common lists of causes of dea and the study of preventable causes of inf mortality.

he Present Position of the Tuberculosis Problem.

Dr. F. J. H. Coutts (Ministry of Health), in opening his discussion, pointed out that the conspicuous fall the mortality-rate from 1851 to 1910 was at the ge-period 20–25 years. Since 1910 the greater ecline had been at later age-periods, while at age-eriods 15–20 and 20–25 there had been little reduction mong males and an actual increase in the female ortality. This disquieting feature of the break-own of young adults from tuberculosis needed ucidation and investigation in each district. Much rther investigation was also needed of the supposed mmunity acquired by children who suffered from eri-bronchial or other mild forms of tuberculosis. e thought that direct measures had played their art in the decline of tuberculosis and quoted intensive xperiments in Sweden and the U.S.A. in confirmation. s regards treatment, good results were being obtained om the induction of artificial pneumothorax and horacoplasty, and the greatest sphere of usefulness artificial light treatment was in the treatment of pus.

Dr. Marcus Paterson said that we taught the fectious consumptive how to avoid infecting his vn family and how to lead a healthy life, but we d not educate the public in the fact that the use of pocket spittoon by the consumptive was a pro-ction for them. Medical students, except in dinburgh, did not receive adequate instruction in e management and treatment of tuberculosis.

Shell-fish.

The cultivation and marketing of shell-fish in od condition was dealt with from the point of view the trade, of the Fishmongers Company, and of the edical officer of health. There appeared to be neral agreement as to the great value of the bacterio-gical tests originated by the Fishmongers Company, upled with inspection of the beds and an intimate owledge of the topographical conditions.

Mr. James Y. Johnston (Prime Warden of the mpany) described the action taken by his Company organise an influential deputation to the Govern-ent, which had resulted in the appointment of ecial committees, one for investigation of the whole estion of pollution of rivers and estuaries, and the her for instituting research as to sewage effluents.

Many medical officers of health spoke of the ready lp afforded them by the Fishmongers Company the case of doubtful shell-fish, and it was pointed t by Prof. J. W. H. Eyre that the Company ceives samples for testing from all parts of the untry, and that the information in its possession to samples and beds is freely available both for e trade and for medical officers of health.

Housing.

The discussion on housing was opened by Councillor lbert Webb, chairman of the Plymouth Housing mmittee, who dealt chiefly with methods of house-rchase, the renovation of existing privately owned uses, and the clearance of congested areas. He mly believed in occupier-owners and, during the st three years, the Corporation had advanced 50,000 to enable tenants of limited means to come owners. The Corporation borrowed at ¾ per cent., and lent at 5¼ per cent., and the ½ per nt. paid management expenses, so that this scheme as self-supporting.

The Corporation had also provided for the sale of unicipal houses to existing tenants on easy terms. he only initial outlay for the tenant was a deposit £10 and the cost of transfer and mortgage deed. or example, a "non-parlour" house, rented at . 9*d.* per week, could be purchased by the payment 9*s.* 6*d.* per week for 30 years.

The Corporation had renovated 147 properties nder Section 3 of the 1925 Act, at a cost to the wners of £25,000, to be recovered from them in payments spread over ten years. Most of this ork was done by agreement with the owners. hey had a new scheme, which was provisionally approved by the Ministry of Health, for reconditioning certain houses in a congested area and demolishing the remainder. Such a scheme might to some extent cater for the casual worker. An experiment in providing small houses for special cases was being considered.

Several speakers congratulated Councillor Webb on the housing activities of Plymouth. From all quarters came the admission that up to now nothing had been possible in the provision of houses for the poorest class and the low-paid worker with a large family.

Dr. C. Lander (Devonport) thought they should recognise that economic rents were frankly impossible, and that housing should be regarded as a State social service. There must be a subsidy and it should come from the National Exchequer. A valuable contribution came from Miss J. M. Upcott, housing manager to the Chesterfield Town Council, on the management of municipal housing estates on "Octavia Hill" lines. She advocated a gradual preparation and education of slum tenants for their removal to better quarters, with perhaps a transition period spent in reconditioned houses.

Milk.

Dr. W. G. Savage opened this discussion with a paper on Milk and Tuberculosis. He regarded the grading of milk as a "magnificent educational gesture." The Tuberculosis Order, as at present worked, was of no value whatever. It would be a continuing expense, with no reduction of bovine tuberculosis and no protection to the public from tuberculous milk. Before the country was committed to the expense of routine veterinary inspection of milk herds, they should be quite clear in their minds as to what they expected this inspection to accomplish and draw up a carefully thought-out scheme, including the coöperation of the dairy farmers.

In the discussion the case for dried milk was put by Mr. F. O. Morris, the case for pasteurisation by Dr. S. G. Moore, and there was a general admission that the eradication of tubercle was so remote that some method of rendering raw milk safe must be adopted in the meantime.

Immunity Methods in Scarlet Fever and Measles.

Dr. R. A. O'Brien showed that the Dick test, the Schultz-Charlton test, active immunisation, and the use of antitoxin have been firmly established in the case of scarlet fever. There was still lacking an antiserum to combat septic conditions which had already appeared, and the problem of the convalescent carrier or return case was unsolved. Convalescents were discharged with hæmolytic streptococci in their throats indistinguishable by any available test from scarlet fever streptococci, but it was not as yet practicable to ask for negative cultures before release, and the medical officer could only adhere to the rule of sending out cases after the restoration of normal health with an absence of discharges from mucous membranes. As regards measles, the utility of the serum of convalescents for conferring either temporary complete protection or for giving active lasting immunity, according to the date after exposure to infection on which the dose was given, was now accepted. The problem for sanitary authorities was to provide and maintain a supply of this serum and to make appeals for volunteer donors.

Dr. W. A. Lethem (Ministry of Health) pointed out that though last year measles killed five times as many children as scarlet fever, the public was still not convinced of its dangers. Schemes for the supply of the serum of convalescents were in operation in several towns in France, Germany, and the U.S.A. Dr. Lethem outlined a scheme for districts in this country. The serum was effective from the eighth to the fourteenth day after the temperature fell. It was preferable to obtain it from adults who could easily spare enough to immunise some 30 children. Adults were usually treated at home by general

practitioners. The medical officer of health should hold a meeting with practitioners to explain the scheme and seek their coöperation in obtaining donors. He should select a laboratory and arrange for an expert from the laboratory to collect the blood. The serum remained potent for many months, if kept at a low temperature. He thought donors would be readily obtained when they understood the great benefit they were conferring on the community without harm to themselves. If the supply was limited, its use should be restricted to children for whom an attack of measles might be a matter of extreme gravity: if more ample, it might be used for all very young children who had been exposed to infection.

Dr. W. T. Benson (Edinburgh), Dr. J. Parlane Kinloch (Aberdeen), and Dr. E. H. R. Harries (Birmingham) confirmed from their experience the views expressed by Dr. O'Brien and Dr. Lethem.

Nursery Schools.

Miss Margaret McMillan described, with the aid of lantern slides, the wonderful changes effected in the pre-school children from the congested areas of Deptford and Greenwich by attendance at the Rachel McMillan open-air garden school. She explained the methods adopted and claimed that by economical management and simple buildings the cost is less than that of an ordinary infant school. The parents contribute, but in return the children get three good meals a day. Nursery schools may be a confession of failure—of failure under existing conditions to secure a good home for each child with reasonable access to playground or garden—but the practical sanitarian acknowledges that congested areas in our industrial towns will hardly be removed in one generation and that there is, in the meantime, a clamant need for many more "Rachel McMillan" schools run by enthusiasts like Margaret McMillan. It is not surprising, therefore, that the resolution, in favour of more open-air nursery schools, and calling upon local authorities to make the nursery classes in the Fisher Act of 1918 operative without delay, met with general acceptance by the Section. Prof. Winifred Cullis, in seconding, emphasised the fact that during these years the foundations of health, character, and education were laid, and that children who had been under the supervision of welfare centres showed fewer defects when they reached the school-entrance age.—Dr. Mabel G. Brodie also testified to the value of such nursery schools; and Dr. E. G. Annis (M.O.H., Greenwich) confessed that Miss McMillan's work for the children of his borough had converted him from a sceptic into a firm believer. The open-air régime and care taken quite prevented outbreaks of infectious disease in the school.

Light Treatment.

Dr. Albert Eidinow described the biological actions of light, while Dr. H. Stanley Banks (Leicester) and Dr. W. Allen Daley (Hull) dealt with the practical application of light treatment to public health work.

Dr. F. G. Bushnell (Devon) spoke on uses and abuses of light treatment, and all the three last-mentioned speakers sounded a note of warning as to exaggerated statements and commercial exploitation of this treatment.

Dr. Daley pointed out, from his experience, the danger of this treatment being added to the list of so-called medical baths and employed without proper medical supervision. He summed up by expressing the opinion that light treatment was a permanent addition to the disease-preventing and disease-curing methods which should be provided by a local authority, particularly for the sun-starved denizens of our towns, that the use of irradiated foodstuffs was not a substitute for light clinics; and that the provision of light treatment by baths committees should be watched with great care.—A resolution was adopted recommending the establishment of public sun and air bathing facilities by local authorities especially for children.

Health of Seamen.

Fleet-Surgeon W. E. Home said that durir this year, for the first time, fairly accurate statisti of the mortality of seamen, occupied and retire had been published by the Registrar-General. The mortality from disease was 75 per cent., and fro injury five times greater than those of "all males The cubic space of British seamen had been increas from 72 cub. ft. to 120 cub. ft., while that of t lascars had remained at 72 cub. ft. Coincidently, t phthisis death-rate of British seamen had declin by 40 per cent., and that of the lascars only 15 per cent. The seaman lived in his ship for hours in the day, and his living accommodati should be passed by a health authority. Some of t seaman's needs were: care of water-supply, was places, good galleys, good w.c.'s, drying-rooms, a accommodation aft.—At a conference of p sanitary authorities, held on Thursday, July 19t the following resolution was unanimously adopted:

That the Council of the Institute be recommended direct the attention of the Government to the desirabili of the care of the health of the men of the Merchant Serv being placed in the charge of the Ministry of Health.

The motion was proposed by Fleet-Surgeon Hom and seconded by Alderman F. Askew, chairman, H and Goole Port Sanitary Authority, who toget sent the motion up to the Council of the Institu to get it on the agenda of the Conference. T motion was supported by Commissioner H. Miller, the St. John's Ambulance Brigade, in an excelle speech, and its unanimous acceptance was ensur from the first.

National Health Insurance Service.

On the last day of the Conference Mr. Henry Less in a presidential address, showed how financial c siderations were retarding the proper developm of the Service, and Mr. W. Gill Hodgson, clerk the Liverpool Insurance Committee, expressed opinion that the present scheme should be perfec by the addition of specialist and consultant servi with laboratory aids and of dental treatment bef any further classes of persons, such as dependa of insured persons, were brought in.

DONATIONS AND BEQUESTS.—Sir Henry Samm Bart., of the Manor House, Willerby, Yorks, shipow left £23,000 for charity, including £10,000 to the I Infirmary, £5000 each to the Seamen's Mission, H and the Henry Samman Chamber of Commerce End ment, Hull, £1000 each to the Port of Hull Society Sail Orphan Homes, and to Hull Seamen's and Gen Orphanage, and £500 to Victoria Hospital for Children, H —The Right Hon. Satyendra Prasanna, Baron Sinha Raipur, of Delhi, India, and of London, left Rs.10,000 e to the hospital attached to the Belgatchia Medical Coll the trustees of the Sadharan Brahmo Samaj of Cornwa street, Calcutta, the trustees of the Bhowanipur Sanmi Brahmo Samaj, the Sambhunath Hospital, Bhowani and the Calcutta Orphanage of Bulloram, Deys-str Calcutta. And if he had not already made provision he had intended to do in his lifetime) for the mainten of the Middle English School and Charitable Dispen which he had built and for many years maintained at Rai then Rs.50,000 upon trust for investment and the inc applied for such purpose.—Mrs. Emily Crossley, of H gate, left £2000 to the Ancoats Hospital, Manchester, a £1500 for the general maintenance of that hospital £500 towards the general maintenance of the Convales Hospital at Warford, Cheshire, in connexion with Ancoats Hospital.—Mr. Samuel Palmer Cooper, of Mos Birmingham, left £1000 each to the General Hosp Birmingham, Queen's Hospital, Birmingham, the Birm ham and Midland Free Hospital for Sick Children, an Dr. Barnardo's Homes; £500 each to the Birmingham Midland Eye Hospital, the Birmingham and Mid Homœopathic Hospital, the Birmingham Royal Insti for the Blind, the National Institution for the Blind, the Children's Hospital, at Cold Ash, Newbury, if his n Mary Katherine Cooper, is matron there. After o bequests the ultimate residue of the property is left bet the General Hospital, Birmingham, Queen's Hosp Birmingham, the Birmingham and Midland Free Hos for Children, and Dr. Barnardo's Homes.

Reviews and Notices of Books.

IOLOGICAL INTRODUCTION TO THE STUDY OF NEUROLOGY AND PSYCHOPATHOLOGY.

Introduction biologique à l'étude de la neurologie et de la psychopathologie. By C. V. MONAKOW and R. MOURGUE. Paris: Felix Alcan. 1928. Pp. 416. Fr.80.

THOSE who endeavour to keep in touch with the ilosophical background of biology are aware of e existence of a reaction against the confident echanist and materialist theories of the last century. the English-speaking world Prof. Whitehead, of. Lloyd Morgan, and General Smuts are among ose now seeking to construct new biological conpts which shall be more adequate to explain the haviour of living organisms. No biological hypoesis which aims at transcending pure mechanism n fail to be indebted to Bergson, who 30 years ago as a voice crying in a wilderness of determinism. of. von Monakow and Dr. Mourgue freely acknowlge this debt in the pages where they impugn rrent concepts in neurology and psychiatry on ounds which Bergson has rendered familiar. They ate that pathological phenomena are considered in olation from the organism; also that the existing nception of function is too static and ignores the ne factor. They believe that evolution is not fficiently recognised to be a qualitative as well as quantitative change, and that language itself, ring to its mode of development, is unsuited to deal th the essential mobility of function. Owing to ese disabilities modern neurology tends to see in thological states of the nervous system no element ve functional deficit, and does not take into account e compensatory efforts, evoked by injury from e organism, which distinguish living creatures m machines. To overcome these defects of method e authors find necessary new concepts which require w terms for their designation, and thus they roduce us to "klisis" and "ekklisis," "protodiasis," and "diaspasis," "hormétères" and "noormétères," "syneidesis" and "hormè." The most portant of these conceptions appear to be the two t named. "Syneidesis" is described as "conscience logique" and is a principle of auto-regulation oked to explain the efforts of an organism to mpensate for its defects. "Hormè" is the undifferentiated drive from which instincts derive their pulsion and recalls Bergson's "élan vital."

Armed with these new weapons of thought Prof. n Monakow and Dr. Mourgue range over the whole ulm of neural function from embryology to religion, d from the conception of causality to the permeility of the choroid plexuses. After an introductory apter they trace the development of character in ms of the integration of instincts. The evolution movement, orientation, and language is then consered. The authors next deal at length with disegration of neural function, giving special conseration to aphasia, and severely criticising the ories of an anatomical localisation of speech entres." Next come chapters devoted to the choneuroses and the psychoses, schizophrenia ng taken as an example of the latter. The book cludes with a review of the evidence that abnormal meability of the choroid plexuses plays a part in ætiology of disease of the nervous system.

Criticism of this book is inevitably disarmed by width of its scope, the laudability of its aim, and ingenuousness of its title. The names of the thors are a sufficient guarantee that the theories veloped are firmly based upon an expert knowledge the histology of the nervous system and a wide nical experience. That such authorities should be profoundly discontented with current physiopathological ideas is of considerable moment, and their attempt to provide a more truly biological basis neurology and psychiatry cannot fail to be allenging and stimulating. How far they have succeeded in their object must be left to the decision of the individual reader. Those who are satisfied with a mechanistic physiology are unlikely to be led to alter their minds. Those who regard such concepts as inadequate to represent the living reality may perhaps find an effective substitute in "syneidesis" and its confrères. But many to whom such principles are incomprehensible will probably finish the book a little disheartened. Is it possible that owing to the structure of our minds and language we are of necessity condemned to employ scientific methods which can never tell us the whole truth about reality? Or may we hope with Prof. von Monakow and Dr. Mourgue that in time we shall succeed in forging new instruments of thought with which to enlarge our apprehension?

ANTHELMINTICS AND THEIR USES IN MEDICAL AND VETERINARY PRACTICE.

By R. N. CHOPRA, M.A., M.D. Cantab., Major I.M.S.; and ASA C. CHANDLER, M.Sc., Ph.D. London: Baillière, Tindall and Cox. 1928. With 5 plates and 65 figures in the text. Pp. xii.+291. 22*s.* 6*d.*

THIS book is written to display for medical and veterinary practitioners both recent and time-honoured methods of attacking helminths. The prime consideration in anthelmintic treatment, it is insisted, must be the patient's safety. The value or otherwise of diet and purgatives, the method of administration of the latter, and the criteria of cure are discussed. A chapter on helminthological considerations bears evidence of haste in preparation. The key which it contains, and which purports to deal, among other matters, with the commoner and more important adult nematodes parasitising man, is in many ways unsatisfactory. No mention is made of ascaris, trichuris, male threadworms, and the hookworms; the description of hydatid cysts seems to imply the necessary presence of scolices, and in the figures of ripe segments of *Tænia solium* and *T. saginata*, described as being drawn to scale, the scales are not correct. The statement that microfilariæ are injected by mosquitoes will not find general acceptance. Several proper names are confusingly misspelt. The chapter on correlation between the chemical composition and anthelmintic efficiency of drugs is a valuable one; full acknowledgement is made of the work of Caius and Mhaskar.

The use of various anthelmintics are considered in detail and this part of the book will be useful for purposes of reference. Most readers will turn to those drugs which are popular at the moment. It is suggested that carbon tetrachloride produces on the mucosa an anæsthetic protective action which limits absorption after doses of moderate size. The implication appears to be that small or divided doses must prove more dangerous than single doses of 3 to 4 c.cm. Evidence for this conclusion would be welcome. Commenting on the widely accepted explanation that poisoning attributed to this drug is really due to traces of carbon disulphide, the authors point out that this lacks laboratory evidence and that the dose of the carbon disulphide for a foal is 1 to 2 drachms. At the same time they accept the assumption that it is some sulphur compound which makes the drug toxic. The reservations which they advise in the administration of carbon tetrachloride entail a close personal examination of every patient. It is once more stated here that Schüffner and Vervoort advised oil of chenopodium in dosage of 3 c.cm.; reducing drops on the international dropper to cubic measurement, their dosage was really 1·2 c.cm. After noting that Ashford treated two million cases with thymol without a single fatality, the authors state that chenopodium and carbon tetrachloride are less dangerous than thymol for field work (though the records of neither approach in safety this cited example) and have largely supplanted thymol in the hands of most practitioners who have kept abreast of the times. We deprecate the implication that the

many authorities who favour treatment by thymol are old-fashioned. The chapters on antimony and emetine used mainly in schistosomiasis, are valuable.

The book as a whole is uneven, but since it reflects the views of men who have had considerable experience in the use of anthelmintics it will be studied with interest by those practising in the tropics.

SHORT ESSAYS ON MEDICAL TOPICS.

By C. O. HAWTHORNE, M.D. London: John Bale, Sons and Danielsson, Ltd. 1928. Pp. 246. 4*s*. 6*d*.

THIS little book contains some 50 essays, from which it will be gathered that many of them are not longer than the average leading article. Hence, as the subjects dealt with vary extremely, not only in theme but in importance, there are places in which the author is driven to being arbitrary, for he has allowed himself so little space in which to explain his views and no space at all for argument with those who might differ from him. But we do not think that many will want to differ, for the author, in discussing some of the most important professional topics, has dealt with them fairly, brought out the salient points, and delivered well-balanced judgments.

SECTION-CUTTING.

An Introduction to the Technique of Section-Cutting. Edited by FRANCES M. BALLANTYNE, M.A., Assistant in the Zoology Department, University of Glasgow. Edinburgh: E. and S. Livingstone. 1928. Pp. 80. 3*s*.

THIS little book has been compiled from the notes of the late Mr. Peter Jamieson, for many years assistant in the department of zoology in the University of Glasgow. It sets forth clearly and briefly the basal technique of section-cutting, and will no doubt find a place in the junior student's library. It is, however, quite elementary, and while, within its limits, its teaching is admirable, it contains little more than the student can learn from an hour's personal instruction and a little practice. If a medical student decides to be content with this manual in place of a more ambitious work he should disregard the statement on p. 49 that formalin as a fixative is only satisfactory for such objects as the eggs of frogs and newts.

KALA-AZAR.

A Handbook for Students and Practitioners. Second edition. By L. EVERARD NAPIER, M.R.C.S., L.R.C.P. Lond., in charge of Kala-Azar Research, Calcutta School of Tropical Medicine. London: Humphrey Milford, Oxford University Press. 1927. Pp. 203.

To those who practise in England kala-azar is merely of academic interest; but to the student of tropical medicine this disease is of paramount importance, for it is one of the dramatic infections of the tropics of which our knowledge has made rapid strides during recent years. Only some 16 years ago kala-azar was regarded as inevitably fatal; and now we learn it is possible to predict a cure in over 90 per cent. of cases. The second edition of Napier's Kala-Azar is thus opportune. Into its 200 pages a vast amount of information is compressed. Especially valuable is the account of the minute epidemiological investigations which led up to the modern conception of the transmission of the disease by *Phlebotomus argentipes*. These demonstrate clearly what can be accomplished by systematically applied observations in a limited area such as the town of Calcutta. The tropical practitioner will welcome a reasoned account of the treatment of kala-azar by the newer pentavalent compounds of antimony; he will, moreover, appreciate the numerous clear illustrations and graphs and the exhaustive bibliography.

ANAEROBES.

Données récentes sur les microbes anaérobies et leu rôle en pathologie. By W. WEINBERG an B. GINSBOURG. Paris: Masson et Cie. 192 Pp. 291. Fr.35.

Weinberg and his colleague have performed a grea service to bacteriologists in publishing this review the work on anaerobes published between 1918 an 1926. The review is accurate, comprehensive, an is informed throughout with the authors' profoun knowledge of the subject. The bibliography contai some 1400 references. If there is a fault it is tha certain organisms are included which may fail t stand the test of further investigation; but this better than omitting any which subsequently prove t be of importance. Bacteriologists will be grateful t the authors for such an excellent work of reference

---

JOURNALS.

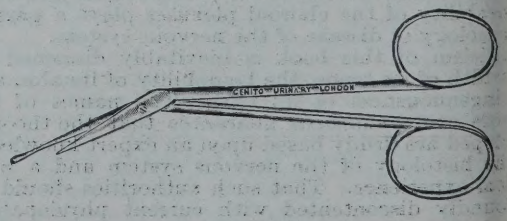
THE CRIPPLES' JOURNAL. Vol. V. No. 17. Jul 1928. 1*s*. 6*d*.—The publication of the April numb of this journal closed four years of work, and th present issue inaugurates the passing of the journ from being the official organ of the Central Counc for the Care of Cripples into an independent public tion run by its own advisory council and wit definitely international aspirations. This adviso council, presided over by Sir Robert Jones, will composed as follows: Dame Georgina Buller, Dan Agnes Hunt, Mrs. Townsend, Sir William Wheele Sir John Lynn Thomas, Rev. Ratcliffe Barnett, S William Lawrence, Bart., and Mr. A. H. Wood (Gre Britain), Mr. Edgar Allen and Dr. Robert Osgoo (America), Dr. Calvé (France), Dr. Murk Jans (Holland), Prof. Putti (Italy), Dr. Rummelh (Norway), and Dr. Biesalski (Germany). The poli of the journal will be towards promoting unity effort in bodies already dealing with one field social work or another in connexion with the interes of cripples, and it is intended to provide informati regarding all work in other countries bearing on th policy, and to print articles with the special obje of instructing voluntary workers in clinical and traini centres. Much stress will be laid upon the publishi of articles of an educational nature while, if t financial future of the journal allows, the price w remain at its present modest figure. We wish o contemporary all prosperity in its ambitio departure.

New Inventions.

PROBE-POINTED SCISSORS

FOR USE IN REMOVAL OF SALIVARY CALCULI.

IN removing calculi impacted in Wharton's du I have found the probe-pointed scissors here ill trated extremely useful. The probe is introduc into the duct as far as the stone, the scissors th lay open the duct, when the stone is usually extract without difficulty.



The instrument has been made for me by t Genito-Urinary Manufacturing Co., 28A, Devonshi street, W.1.

Birmingham. HAMILTON BAILEY, F.R.C.S. Eng

THE LANCET.

LONDON: SATURDAY, AUGUST 4, 1928.

EPIDEMIC CONSTITUTION.

FREIHERR VON PIRQUET'S discovery of the skin reaction to tuberculin not only enabled us to realise the universality of tuberculous infection, but has also proved to be the forerunner of a series of investigations of a similar character which have brought within the compass of one scientific theory most of the epidemiological phenomena exhibited by a large group of the acute communicable diseases. The Schick and Dick tests, although the significance of a positive result is different from that in Pirquet's reaction, have been equally fruitful in the genesis of ideas as to the prevalence of the infections of scarlatina and diphtheria, and these ideas have been found applicable to the epidemiological problems of other droplet-borne infections, such as poliomyelitis, meningococcal meningitis, and epidemic encephalitis. Prof. ULRICH FRIEDEMANN'S paper, published on page 211 of our present issue, is an admirable survey of the present state of knowledge in relation to the ætiology of some of these diseases and the extent of latent infection with the virus, whether known or still undetected, of some of these diseases among civilised communities. The essential truth now established is the extent to which the population is constantly immunised, presumably by subminimal doses of the virus, against diphtheria and scarlet fever, a process which Prof. FRIEDEMANN terms "latent epidemisation." The meaning of this phrase has been tersely explained by W. L. AYCOCK[1] in these words, "Of susceptible individuals exposed to measles 1 out of 1 develops the disease; to diphtheria 1 out of 10 develops the disease and 9 out of 10 develop subclinical immunity; to poliomyelitis 1 out of 100 develops the disease and 99 out of 100 develop subclinical immunity, or immunity from abortive attacks." Students of epidemiology will subscribe generally to this view without committing themselves to acceptance of the numerical proportions, and there can be no doubt that the way to this state of agreement has been paved by the American workers on the dermal reaction to diphtheritic and scarlatinal toxins. At the same time, it is only right to remember that ideas of this nature, nebulous perhaps, like many ideas born of clinical observation, found expression long before they were capable of experimental verification, in explanation, for instance, of such facts as the observed immunity of fever hospital residents and nurses without the affliction of previous manifest disease, the peculiarity in relation to scarlet fever and diphtheria contrasting markedly with the behaviour of unvaccinated members of the staff in contact with small-pox. Indeed, it may be said that clinical observations, field inquiries, and statistical surveys had already made the minds of epidemiologists receptive to the idea of "latent epidemisation" and "latent immunisation," although the theory had not actually been given its present acceptance and wide application.

Since FARR made a science of vital statistics English epidemiologists have continued to search for the laws of epidemics, and many of the proceedings of the Epidemiological Society, which is now merged in the Royal Society of Medicine, will repay study to-day. The periodicity of the different zymotics, their incubation periods, age-incidence, and variable case-mortality in relation to the apparent source of infection, the course and peculiarity of single epidemics, the predictability of their behaviour, were all explored for the clue which would lead to the discovery of one thing common to them all, the law which governed their coming and going. FARR brought the art of epidemic prophecy to a high state of accuracy, and satisfied himself by purely mathematical reasoning that there was more behind the decline of an epidemic than mere exhaustion of the number of susceptibles existing at its onset. In more recent years attempts have been made to account for the decline and recurrence of epidemics by variation of the infectivity of the virus, a theory not inherently improbable since changes in virulence are well recognised. Perhaps the most ingenious mathematical attempt to correlate the seasonal and other variations of the incidence of epidemic disease was the application of the periodogram to this type of problem by BROWNLEE.

Working alongside the statisticians—sometimes combining more than one function in a single person—were the bacteriologists and the practical sanitarians, both piling up observations which undermined the old conception of the epidemic without supplying enough material to provide entirely new foundations. The bacteriologist established the existence of chronic or intermittent carriers of infection; the practical investigator of epidemics was more impressed with the importance of mild, anomalous cases of disease. But it was really the field observations of J. A. GLOVER and S. F. DUDLEY, followed by the laboratory study of epidemics in mice by W. W. C. TOPLEY, which established the paramount importance of the population-medium—its constitution, its spacing, its internal movement, and the influx of new members—as controlling factors in the rise and fall of epidemics. Flagrant disease, anomalous disease, infection without disease, intermittent and chronic carrier states are now seen in their true importance and interrelation with one another, and the reactions of Schick and Dick are measures of their combined influence. Many things still remain to be explained, notably the tendency for diseases practically to disappear and then revive with apparent irregularity and with impressive suddenness, like influenza and poliomyelitis, in the absence of abnormal migration, or to occur apparently de novo as in the case of epidemic encephalitis. But we have a solid addition to the body of medical thought in this new theory of the epidemic, which justifies the best part of the established measures for control of the communicable diseases, while revealing the reasons why these in themselves have proved insufficient to abolish the endemic zymotics from civilised communities. The criteria of communicability, too, have been extended, and we can no longer assume that diseases like rheumatism are non-communicable merely because case-to-case associations are untraceable. Further, we have been armed with a new specific preventive in the form of toxin or toxin-antitoxin inoculation, the value and limitations of which are well stated in Prof. FRIEDEMANN'S paper.

THE VACCINATION REPORT.

EARLY this week appeared the Report of the Committee on Vaccination appointed two and a half years ago by the Minister of Health in conjunction with the Medical Research Council. It was a Committee of seven with Sir Humphry Rolleston as chairman,

Dr. J. R. Hutchinson as secretary, and Dr. F. R. Blaxall, Dr. G. F. Buchan, Dr. A. E. Cope, Dr. Mervyn Gordon, Prof. J. C. G. Ledingham, and Dr. J. R. Perdrau as members. The Committee was asked to inquire and report: (1) on matters relating to the preparation, testing, and standardisation of vaccine lymph; (2) on the practical methods which are available in the light of modern knowledge to diminish or remove any risks which may result from vaccination; and (3) on the methods of vaccination which are most appropriate to give protection against risk of small-pox infection in epidemic and non-epidemic periods. The Committee was at the same time given liberty to coördinate the work of investigation on these questions in this country and abroad. The Report is divided into two parts, of which the first deals with each reference in turn, and the second exclusively with the consideration of the nervous conditions which occasionally follow vaccination. A series of appendices complete a volume[1] of 324 pages, which is admirable alike in its lucidity and restraint.

The Committee's reference has given rise to an account of the methods of lymph production in general and especially those employed by the Government Lymph Establishment. The preparation of the vaccine is of peculiar interest, for, with the exception of the original Pasteur method of treatment of hydrophobia, small-pox vaccination is to-day the sole established instance of the use of a living virus as an immunising agent. Although strains of vaccine lymph of diverse origin are used, the vaccination process throughout the world is remarkably constant in character and uniform in feature, and agreement has been reached as to the methods of testing the potency of lymph and as to the minimum standard of potency which can be sanctioned. These tests and standards are now laid down in the Regulations under the Therapeutic Substances Act, and they give, in the Committee's opinion, the desired assurance that the preparation of vaccine lymph is being carried out on approved lines as regards minimal potency and comparative absence of associated micro-organisms. Government lymph, it is interesting to note, is not issued until about two years from the date of its collection, when, owing to the combined action of the glycerine and oil of cloves the extraneous organisms it contains are eliminated or reduced to 5 or less per mg. There is still, unfortunately, a great lack of information as to the minimal dose of lymph necessary to secure adequate immunity from small-pox, and this is a problem awaiting solution by experimental means. Singular promise lies in an observation recently made at the Lister Institute, where vaccine virus, in contact with chick embryo cells, has been found to increase in potency one-thousand fold. Otherwise there is a general consensus that different strains have similar immunising powers. Vaccination in this country has hitherto aimed at securing in infancy the longest possible duration of immunity and at postponing the time when revaccination should become necessary, whereas the American and Canadian practice is to popularise vaccination by rendering it as little incommoding as possible, with the hope that a second or even a third vaccination will not merely be tolerated, but even sought. The Committee now definitely recommends that, in place of the officially advocated four insertions, a trial should be made of vaccination and revaccination in one insertion with a minimum of trauma, and deprecates multiple scarification or cross-hatching. The optional age for vaccination on these lines is regarded as months, and the offer of revaccination might advantage be made when the child enters schoo 5–7 years, and again on leaving it at 14–16 ye Multiple insertion would still be available for s persons as desire to obtain the maximum protec at one stage. Vaccinators are advised to ins twice after vaccination, the second time betw the fourteenth and seventeenth days, and to m it clear to parents that such medical attention is required is obtainable without cost. The sylla of instruction to medical students should, the C mittee feels, be revised in the light of present- knowledge.

The risks of vaccination have markedly diminis since the Act of 1898 came into force, and in so as the risk is from sepsis it is likely to dimi further to a vanishing point. But the second of the Report is, as we have said, given up enti to the risk from disease of the central ner system following vaccination, and there m appear to be a certain want of proportion in devo more than 100 pages to this subject, were it not for fact that the occurrence of post-vaccinal ner disease, however seldom of occurrence, cannot to have a bad effect on vaccination both in its ad istrative and in its medical aspects. Happily Committee is able to point out the extreme ra of such manifestations. During a period of years (1922–27), in which 3 million charges of ly were issued by the Government station, and estimated number of vaccinations performed in country was over 4½ million, 51 deaths were reco from this cause. Particularly rare is nervous comp tion after revaccination and after primary vaccina in early infancy, and on this ground, if on no o early infancy remains the time of choice for pri vaccination. Here is incorporated, at length, report of the committee appointed in 1923, u the chairmanship of Sir Frederick Andrewes, w now sees the light in this country for the first t Although the non-appearance of the Andr Report may have occasioned undue anxiety in quarters, justification of the delay lies in the rea ing commentary which now appears in the ligh further knowledge. The Rolleston Committee u mously acquits vaccinia virus of being the cause of nervous sequelæ, although it ca exonerate vaccination from playing some pa their causation. It is its considered opinion tha coöperation of vaccinia with the viruses of p myelitis or of encephalitis lethargica, or pos some unknown neurotropic virus harboured vaccinee, must for the present be retained working hypothesis of causation. It is hoped the publicity now given to this complication result in an accumulation of clinical and epid logical data which may help along with experim research to solve a problem of great importan quality if not in quantity.

The final recommendation is to the effect that be taken to impress upon the public mind the n and purpose of vaccination. The Commi Report will afford the medical profession fo first time a body of accurate and unbiased inf tion to be used for this purpose, and we believe good prospect of success.

ANTHROPOLOGY AND PARASITES.

THE nasty grey squirrel which came from America and escaped from the Zoo some years to spread all over England, as far north as York

ıd at least to the Cotswolds in the west, carries with everywhere its own special flea; anyone knowdgeable in such matters (whether he should be called pulicophile or a siphonapterologist we do not know) ho picked up a dead *Ceratophyllus wickhami* in the ad would be sure that *Sciurus cinereus* was not far f. And this is the general truth about parasites; ch species is adscript to one or at most two or three sts, and very few are so little particular in their abitats that they range indifferently over a large mber. When the hosts travel they take their rasites with them. It is very unlikely, for instance, at the great plague vector *Xenopsylla cheopis* is tocthonous in England; it lives, or used to live, the rats in the Borough because it had come with host from the tropics. Similarly, the provenance the labourers on the coffee plantations in Brazil n be predicted by finding out whether their preminant hookworm is *Ankylostoma duodenale* or *ecator americanus*. This segregation and isolation of rasites in particular hosts naturally encourages eciation—i.e., separation into distinguishable forms and their occurrence may give us some information th as to where the host has been quite lately and to where and what the hosts' ancestors have been the remote past. The specific differentiation of man lice as they occur now is dubious and uncertain; is supposed that they are largely mixed hybrids some definite species which used to occur isolated the primary human races, and which have become ixed by human migrations and intercourse.

In one way and another, therefore, parasites may row light on a good many general questions, and in e last number of the *Quarterly Review of Biology* ol. iii., p. 225) the possible evolutionary significance the protozoan parasites of monkeys and man is scussed in an interesting way by Prof. ROBERT EGNER, of the Johns Hopkins School of Hygiene. e recognises six amœbæ, seven flagellates, one ccidium, and one ciliate as being genuinely parasitic the human intestine, of which *Entamœba histolytica*, *ospora hominis*, and *Balantidium coli* are definitely athogenic; in the blood we have three malarial rasites, three trypanosomes, and three *Leishmania*. he protozoa of monkeys are naturally not nearly well known, and it is obvious that observations on imals living in captivity in close association with an are not of much significance. The monkey nœba *E. nuttali* is as like the human *histolytica* as can be, nor can their harmless *E. coli* be distinished from those found in man. And with the ception of the *Leishmania* the same correspondence found in the other groups; 11 out of 15 of the man genera, and two-thirds of the human species ave been described from monkeys, though the alarial parasites of monkeys would be better scribed as very similar to, rather than identical ith, that of man. The facts are interesting; their terpretation is difficult, for such a situation may ave arisen because man has a genetic relationship ith monkeys or because he provides in his bowels, s blood, and his economy in general, a similar series habitats. On either hypothesis human parasites ould be more like those of monkeys than those of ats or cows, and there seems to be nothing in the rgument which would convince a determined fundaentalist of error. On the whole, the genetic lationships of hosts and parasites are not very close, nd if the occurrence of monkey parasites in man dicates the line of human descent, what significance re we to attach to the discovery of *Balantidium coli* pigs and guinea-pigs or to the fact that the other atural host of *Pulex irritans* is the badger?

Annotations.

"Ne quid nimis."

THE BUNDABERG REPORT: FATAL STAPHYLOCOCCAL INFECTION.

THE report of the Royal Commission on the Queensland serum tragedy of last January [1] has now been tabled in the Federal Parliament. The findings of the Commission are these:—

The Findings.—1. The injections of toxin-antitoxin mixture administered by Dr. Thomson at Bundaberg on Jan. 27th, 1928, were responsible for the deaths of 12 out of 21 children inoculated, and for the illness of several who survived.

2. The toxin-antitoxin mixture as issued by the Commonwealth serum laboratories was properly prepared and sterile, but contained no antiseptic, and, therefore, did not prevent the growth of micro-organisms accidentally introduced into it.

3. The rubber-capped bottle of toxin-antitoxin supplied to Dr. Thomson at Bundaberg was accompanied by no information as to the presence or absence of antiseptic.

4. The omission of antiseptic was intended to safeguard against the dangers attendant upon freezing, but the issue of this preparation without antiseptic in rubber-capped bottles suitable for repeated usage is an unsound procedure.

5. The toxin-antitoxin mixture in the bottle used by Dr. Thomson was contaminated by him with a pathogenic staphylococcus during a series of inoculations on Jan. 17th, 20th, 21st, and 24th, most probably on the last occasion.

6. The consideration of all the available evidence concerning the deaths at Bundaberg points to the injection of living staphylococci as the cause of the fatalities.

As a result of much experimental work and a critical review of the evidence, the Commission was led to make certain definite recommendations with a view to avoidance of similar tragedies in the future.

The Recommendations.—1. That biological products in which the growth of pathogenic organisms is possible should not be issued in rubber-capped containers for repeated use unless there is present in the material a sufficient concentration of antiseptic to inhibit bacterial growth.

2. That all biological products not containing antiseptic, however issued, should bear a conspicuous printed notice, both on the container and on the package, to the effect that no antiseptic is present; that they should be used immediately on opening, and any remaining product discarded.

3. That biological products should be distributed in bottles or ampoules of clear glass in which it is easier for the medical practitioner himself to detect turbidity or any other defect.

4. That the Commonwealth Department of Health should make full and careful inquiry as to whether it be advisable to substitute anatoxin or some similarly modified immunising agent for toxin-antitoxin.

5. To ensure the adoption of the most approved technique, facilities for special post-graduate training should be afforded to all medical officers entrusted with the conduct of public campaigns to diminish the incidence of disease by immunisation.

Poisoning by diphtheria toxin, it will be noted, is excluded on adequate grounds. The clinical picture in the fatal cases was not that of fatal diphtheritic toxæmia; at the autopsy the suprarenal glands were found to be normal, and the children who recovered did not show any of the characteristic sequelæ of diphtheria. No free toxin was found in the prophylactic remaining in the fatal bottle nor in many duplicate bottles taken from the batch of prophylactic incriminated. The possibility of tetanus was carefully considered and rejected. The evidence for staphylococcal infection was that the remaining fluid in the bottle used was noted as cloudy on the day after the injections, that the contamination had "almost certainly" occurred three days before the fatal injections were given, and that the remaining fluid in the bottle yielded a pure culture of staphylococcus. Of the 21 children injected 12 died; in all 9 survivors, of whom 6 were ill, abscesses developed at the site of injection, and from 5 of these abscesses a staphylococcus apparently identical with that in the fatal

[1] THE LANCET, 1928, i., 249, 1293.

bottle was recovered in pure culture. The estimate is that five million cocci, together with their products of growth, were injected into the children. The children began to suffer within six to eight hours from vomiting, diarrhœa, fever, early unconsciousness, retention of urine, and, in the younger ones, convulsions, death occurring within 24 hours in several instances. With two doubtful exceptions no metastatic staphylococcal abscesses developed in any of the survivors. The coccus isolated did not seem to possess any unusual cultural or fermentative properties and closely resembled varieties of *Staphylococcus aureus*, though it produced "a buff coloured" and not "a typically orange" deposit. An antiserum to the coccus agglutinated aureus strains typically. Apparently neither culture nor filtrate produced in laboratory animals, including *Macacus rhesus*, a picture resembling that seen in the children, though small doses given intravenously to rabbits killed in 12 to 24 hours with convulsions. Evidently higher monkeys were not available for injection. The Commissioners very fairly state that their findings are based on evidence that is suggestive rather than conclusive, that unfortunately defects in the clinical study of the cases and lack of specialised bacteriological and pathological examination of the children who died left serious gaps in the evidence, and that "short of the unthinkable experiment of injecting the living staphylococci into children, it is not possible to offer rigid proof . . . for there is not within our knowledge any previous experience of the subcutaneous injection of large numbers of living staphylococci into young children." Bacteriologists, we think, will agree that the Commission could not do otherwise than conclude that the contaminating staphylococcus and its toxins caused the deaths, and that the tragedy would have been avoided had the prophylactic contained sufficient antiseptic, a practice which is probably universal in England, America, and the Continent. So far as we can find, there are on the English market no prophylactic preparations without adequate antiseptic. On such points the Therapeutic Substances Act provides for any control considered necessary.

Two other points in the report merit attention. The Commission recommend inquiry directed towards the replacement of toxin-antitoxin mixtures by toxoid or anatoxin. No reasons for this recommendation are given in the text of the report available at the time of writing. The needles used in immunising the children had apparently been kept in methylated spirit. The phrase "sterilised in methylated spirit" occurs in the report. It is well known, and has been emphasised by T. J. Mackie[2] in a recent important review of the preparation of catgut, that methylated spirit possesses a restricted bactericidal power and that it cannot be relied upon to sterilise surgical apparatus if resistant or spore-bearing microbes are in question.

THE TRAFFIC IN NARCOTIC DRUGS.

In accordance with a precedent initiated last year, the annual report of the British Government to the League of Nations (1927) on the traffic in opium and other dangerous drugs, has been communicated to the press. It deals with the administration of the Dangerous Drugs Acts, 1920 and 1923, in Great Britain, and furnishes abundant statistical information as to the manufacture in this country of morphine and heroin and their salts, and as to the import and export of opium and its alkaloids, and of cocaine during 1927. Reference is made to the extent of the international illicit traffic alluded to in THE LANCET of July 21st (p. 133). While several seizures of drugs were made at English ports on ships of British nationality, it is satisfactory to learn that no information had been received that any firm in Great Britain had been engaged in smuggling drugs abroad, nor have any seizures of drugs of British manufacture been reported during the year. It may be w worthy of consideration whether, if all members the League of Nations and States parties to T Hague Opium Convention of 1912 had passed—a enforced—legislation like the Dangerous Drugs A 1920 and 1923, which gave effect to that Conventi the international situation in regard to the comme in narcotic drugs would not be more satisfact than it is. The amount of British morphine ma factured and exported continues to fall. While a f years ago some 14 tons were in one year exported, 1927 the amount was 66,107 oz. The figures heroin are less satisfactory, 17,427 oz. having b manufactured against 11,113 oz. in 1926; 11,165 were exported against 6799 oz. in 1926; 4673 oz. w consigned to France, a considerable increase on t amount for 1926. Of 107,042 lb. of raw opi arriving through the approved ports of Lond Liverpool, and Southampton, no less than 86,080 came from India, and only 19,888 lb. from Turk As the morphine content of the Indian drug was 10 per cent., against 11·12 per cent. in the Turkish, t old prejudice against the pharmaceutical use of t Indian variety, by reason of its alleged poverty in t alkaloid, appears to have been ill-founded. Hithe there has been no production of cocaine from t leaves, or by refining crude cocaine, in Great Brita but in 1927 a licence was granted to Messrs. May a Baker, Ltd., of Wandsworth, to carry on experime in such manufacture. The licence precludes t marketing of such produce without the spec sanction of the Home Office.

Two important seizures of cocaine have been ma in London this year, one of Japanese manufact smuggled in by a Lascar on a vessel from the F East; the other of German manufacture exported Lithuania and thence smuggled in by a Lithuani resident in London. There were 60 prosecuti under the Dangerous Drugs Act in 1927; 45 pers were convicted and fined, or imprisoned, or de with under the Probation of Offenders Act, wh five were recommended for deportation. It appe that a considerable amount of morphine (65,746 o was used in 1927 for the manufacture of codeine. T alkaloid is not scheduled as a dangerous drug, althou in the first draft of The Hague Convention it w included. The question of applying to it the p visions relating to morphine and heroin has engag the attention of the Opium Advisory Committee Geneva.

ACUTE EMPYEMA.

In a recent article on the treatment of acu empyema, Dr. Antoine Basset maintains[1] that th is no longer any uniformity of method in de ing with this condition, nor is there any soun established doctrine to guide the practitioner wh faced with this emergency. Prior to the epide of influenza in 1918, the treatment of empye was similar to that of any other collection pus—viz., immediate evacuation and draina To render these more effective, costal resection w usually practised. The customary method w adopted for the treatment of empyema complicati broncho-pneumonia during the earlier months the pandemic, but the results were profoundly d appointing. In certain of the American milita camps the post-operative mortality is said to ha reached the figure of 84 per cent. As a consequen less drastic methods were advocated; aspirati with irrigation of Dakin's or Murphy's soluti replaced the classical operation of costal resecti and open drainage. The advantages to be deriv from conservative treatment, at least as a tempora measure, were discussed at the Twenty-third Congr of the French Surgical Association in 1920, and t matter has been debated ever since. Dr. Bass advises postponement of operation when empye complicates acute pulmonary disease; in such cas

[2] An Inquiry into Post-Operative Tetanus. A Report to the Scottish Board of Health. See THE LANCET, 1928, i., 1187.

[1] Traitement des pleurésies purulentes aiguës de la gra cavité, Arch. med.-chir. de l'appareil resp., December, 1927

considers it advisable to wait until the pneumonic process shows signs of retrogression. Meanwhile the patient may be relieved by aspiration of pus and supported by medical treatment, including vaccine and serum therapy. When operation is decided on, local anæsthetic should be used and as a rule the most effective drainage will be secured by resecting 4 or 5 cm. of the tenth rib in the posterior axillary line. Pneumococcal empyema in children is often a relatively benign infection, and for these cases repeated aspirations may suffice. They are certainly to be preferred during the acute pneumonic stage. Rib resection should also be avoided in early childhood—i.e., before the age of 18 months. But there is an exception to the statement that in the presence of an acutely diseased lung preliminary treatment by aspiration is the method of choice. A putrid empyema, or one associated with gangrene, should be freely drained at the earliest possible moment whatever the condition of the subjacent lung. Dr. Basset lays stress on the importance of a careful cleaning of the empyema cavity by gauze swabs at the time of operation. Neglect of this precaution may lead to blocked tubes and ineffective drainage. Short wide tubes should be used and the employment of a Tiegel's valve will permit free exit of pus while preventing the entrance of air during inspiration. A simpler method of obtaining the same end is, of course, to connect the drainage-tube with a reservoir containing antiseptic solution.

INTESTINAL BACTERIA IN PERNICIOUS ANÆMIA.

It is rather more than 20 years since Dr. C. H. Carter pointed out that *Bacillus welchii* was abnormally abundant in the fæces of cases of pernicious anæmia, and rather before that time Dr. William Hunter began to urge the ætiological importance of gastric and intestinal streptococci. Both organisms are hæmolytic in the sense that they can produce intracellular toxins which are capable of dissolving red corpuscles both in vitro and in the body of experimental animals. The capacity of *B. welchii* in this respect is especially powerful, and Dr. H. G. M. Penry and others have worked out the conditions under which its hæmotoxin is produced, how it acts in the body, and how it stimulates the production of an antitoxin. That the chronic anæmia of pernicious anæmia is directly due to any such antigenic hæmolysin is on general grounds very unlikely; the body would become actively immune, and if it did not it should be easy enough to make it passively immune by injecting *welchii* antitoxin; this has no effect on the course of the disease. But if *B. welchii* and streptococci do not cause the disease directly by their hæmolysins, it does not follow that they play no rôle in its pathogenesis. The absence of acid from the stomach is a grave abnormality and is obviously likely to upset the bacteriology of the alimentary tract, at any rate in its upper part. An abnormal abundance of organisms has been described by a number of observers, and the whole subject is reviewed in a comprehensive way in the current number of the *Journal of Pathology and Bacteriology*, by Dr. Stanley Davidson, of Edinburgh, who has elaborately studied 41 cases of pernicious anæmia along with normal controls and examples of other diseases, examining the fæces and the gastric and duodenal contents; these two last cannot, he says, be separated, since the patulous pylorus of pernicious anæmia leaves the stomach and duodenum in free communication. His results are, briefly, that in pernicious anæmia there is a great numerical increase in *B. coli*, streptococci, and *B. welchii*, both in the stomach and in the stools. These microbes are normal inhabitants of the human alimentary tract, and a careful investigation of their varieties failed to show any qualitative difference between those found in healthy persons and those from pernicious anæmia. He concludes that there is no evidence that any individual type of organism is specifically related to pernicious anæmia. At the same time, he attributes great ætiological importance to the quantitative increase of bacteria, especially at levels in the small intestine which in normal persons are relatively free from bacteria. It may be supposed that these act by producing, directly or indirectly, substances which, passing by the portal circulation, impede the action of the liver. The gastro-duodenal sepsis runs parallel with the achlorhydria, and both continue unaltered after cure by liver. On this view pernicious anæmia is a pathological but not an ætiological entity. The changes described in the flora of the alimentary tract are not quite invariably present, and other factors may less commonly play an important part. Dr. Davidson mentions a hereditary or constitutional element in the disease, but the evidence for this is rather nebulous.

MEDICAL HISTORY STATEMENTS.

A RECENT paragraph in the *Solicitors Journal* draws attention to some observations of the county court judge at Birmingham upon the practice of medical witnesses. In workmen's compensation and other cases it is often necessary that the medical practitioner should ascertain the patient's medical history before diagnosis. But the statement which the patient gives may be closely connected with the very facts which are in dispute. In the Birmingham case apparently the plaintiff's representative suggested that the medical witness had exceeded his professional duties in obtaining such a statement. On the other hand, on behalf of the defendant it was stated that the statement was obtained by the medical witness in the presence of the patient's own doctor and was written down in the presence of both. His honour Judge Ruegg, K.C., observed that nothing unusual had been done, but that it was becoming a habit with doctors to take particulars of this kind, and then to come into court and give evidence of the contents of the statement. Upon this position two comments seem proper. In the first place it is always the duty of a medical witness to distinguish between facts which are within his own direct knowledge and matters of which he has merely been told. This distinction is notoriously of great significance in the process of certifying a patient under the Lunacy Act. The second comment is that which the county court judge himself made. He thought it objectionable that doctors should obtain statements in the way mentioned, because, if a patient knew that statements were to be obtained in that way, he would hesitate to go to a doctor. Subject to these two comments it is clear that a medical witness's evidence may be useless, unless he has been made aware of the patient's medical history, and the witness is entitled to state how far the patient's condition is consistent with, or could be explained by, that history. It does not appear that an experienced county court judge could ever be misled by medical evidence properly so obtained and tendered.

SCHOOL MEDICAL OFFICERS AND THE NOTIFICATION OF MENTAL DEFECT.

THE passing of the Mental Deficiency Act, 1927, has made it necessary for the Board of Education to revise their regulations governing the notification of children and the draft of the new regulations has recently been published. These will come into force on Oct. 1st, 1928. They are decidedly shorter and simpler than the old ones, and in addition to containing certain minor alterations consequent on the changes in the Act, they make an alteration which should be welcome to local education authorities and their medical officers. The Act requires, in the case of defective children of 7 years and upwards, who are incapable by reason of mental defect of receiving benefit or further benefit in special schools or classes, or who cannot be instructed in a special school or class without detriment to the interests of the other children, that their names and addresses shall be notified by the local

education authority to the local mental deficiency authority, who will then be responsible for them. Under the old regulations, if the child whom it was proposed to notify was not an idiot, imbecile, or moral imbecile, the Board of Education required that their sanction should be obtained before such notification was made. Under the new regulation this has been waived, and cases in future can be notified on the certificate of the school medical officer without reference to the Board. There is a provision that in the case of the local education authority being in doubt regarding any child so certified, they may refer the matter to the Board before discharging their statutory duty of notification, and such reference to the Board is compulsory in the case of blind or deaf children coming under Section 69 of the Education Act, 1921. It may happen that a child is certified by the medical officer as not being incapable of receiving benefit from instruction in a special class or school, but is nevertheless considered to be in need of supervision, guardianship, or institutional care. In this event the case is to be referred to the Board, and if the Board certify that there are special circumstances which render it desirable for the child to be dealt with in this way, it then becomes the duty of the local education authority to notify the case to the local mental deficiency authority. In the case of children about to be discharged from special schools on or before attaining the age of 16 years, the local education authority may still, as previously, decide as to whether notification should be made without reference to the Board. We think that the alterations which have been made will tend to simplify administration, and they are doubtless inspired by an increased confidence on the part of the Board in the efficiency of school medical officers and local education authorities.

PHARMACY AND BIOCHEMICAL DISCOVERY.

ADDRESSING the British Pharmaceutical Conference at Cheltenham on July 24th, the chairman, Mr. R. R. Bennett, B.Sc., F.I.C., selected certain aspects of biochemistry of importance to those engaged in the practice of pharmacy, dealing in succession with the practical applications of the study of hormones and vitamins. More than ever before the pharmacist, he said, is dealing with remedies which can only be assayed and standardised by biological methods, a fact which was bringing into prominence the increasing work carried out at the Pharmaceutical Society's pharmacological laboratories. The General Medical Council had been criticised for its failure to introduce biological methods of standardisation into the current British Pharmacopœia, but, said Mr. Bennett, the Council should not be blamed for that; at the date of its issue the Council could not have prescribed biological tests as there were no official standards for such tests, nor had the Council then any power to enforce such standards in the absence of a laboratory where tests could be made. It was only the coming into force in August, 1927, of the Therapeutic Substances Act of 1925 which had brought into being a Joint Committee charged with the duty of prescribing standards, tests, and units of standardisation for therapeutic substances, the purity and potency of which could not be adequately tested by chemical means. Standards had now been defined for a number of such substances, laboratories had been appointed to prepare and keep the standards, and machinery for controlling their application had been created. The Pharmacopœia Commission which would soon come into existence would, he said, accordingly be able to include in the next edition of the Pharmacopœia any therapeutic substance for which a standard of reference had been defined by the Joint Committee, and to introduce a biological method for standardising any substance for which a standard had been set up. Mr. Bennett congratulated the Pharmaceutical Society on its readiness to adapt itself to these fundamental changes, and concluded with the remark that the future of pharmacy will depend upon the continued cultivation of the scientific habit of mind and upon the power of c fronting new conditions and new difficulties w systematic knowledge and perfected technique.

ETHYL PETROL.

THE internal combustion engine has its marl likes and dislikes, and, last autumn, the first c signment reached this country of a kind of fuel wh had been found in America to abolish a tiresc form of engine trouble; but this ethyl gasoline, a was called, contained a small proportion of l tetra-ethyl in the manufacture of which distress cases of lead poisoning were known to have occur The question arose whether the consumer mi not also run some risk from its use, and a discuss in the House of Lords last February elicited statements that Sir William Pope regarded l tetra-ethyl as a poison likely to be absorbed thro skin abrasions and by the lungs, and that P H. B. Baker believed it might reach the body thro the unabraded skin. As a result of this discuss the Minister of Health agreed to appoint a Dep mental Committee to inquire into the possible dan to health resulting from the use of motor spirit this kind. This Committee,[1] which included tinguished chemists, toxicologists, and med administrators, has now issued an interim repo the message of which may be stated at once to " there is no evidence to show that the use of et petrol as a motor fuel involves more dangers to hea than the use of ordinary petrol." This favoura report was not unexpected in view of such evide as is presented in the report[3] by Dr. Alice Hamilt of Boston, to the International Labour Office. Fr this report it was already clear that scrupulous has practically eliminated risk from the manufact of tetra-ethyl lead and also from the process blending it with petrol. Moreover, the workers employed can be carefully supervised and f protected. In regard to the chauffeur and the gar man who fills petrol into cars, a committee of exp issued in 1926 a considered report based on expi mental work. No definite signs of lead absorpt were detected after exposures of two years, and good grounds were found for prohibiting the use ethyl petrol as a motor fuel, provided that its dis bution and use were controlled by regulati Evidence, however, was forthcoming that, q apart from the use of lead in petrol, lead dust d accumulate wherever motors are garaged, and t whether it originates from paint, from rubber, or fr accumulators the risk of poisoning seems compar to that which might arise from ethyl petrol. risk from lead, however, is regarded as definitely than that from carbon monoxide, which nowad necessitates free ventilation of garages and mo sheds.

The Departmental Committee's report bri Dr. Hamilton's monograph up to date and cont the evidence of Dr. J. P. Leake, of the United St Public Health Service, who assured the Commi that although careful search had been made possible injury to health from the use of ethyl pet no instance of injury had come to light. It is t that there is no compulsory notification of indust lead poisoning in the U.S.A., but Dr. Leake's inq extended over private sources, press-cutting bure and the health authorities of each separate St and in view of the publicity which has been dr to this fuel it is hardly likely that any cases of poiso should have escaped notice. In regard to the

[1] The members of the Departmental Committee appointe April 2nd, 1928, are Sir Frederick Willis (Chairman); Mr. Bridge, F.R.C.S.E.; Sir George Buchanan, M.D.; Mr Chaston Chapman, F.R.S.; Prof. W. E. Dixon, F.R.S.; M W. R. Galwey, M.B.; Mr. C. H. Lander, D.Sc.; Sir Ch Martin, F.R.S.; Mr. D. R. Pye; Sir Robert Robertson, F.R Sir William Willcox, M.D.; with Mr. S. F. S. Hearder (Secret

[2] Interim Report of the Departmental Committee on E Petrol. Cmd. 3159. H.M. Stationery Office. 1928. 4d.

[3] Revised by the Correspondence Committee on Indus Hygiene and published as Brochure No. 87 of the encyclop entitled "Occupation and Health." Geneva, 1928.

o inhaling lead from ethyl petrol, Sir Robert Pbertson was able to assure the Committee that the fi t half of petrol evaporated from the mixture is e irely free from lead tetra-ethyl. The risk to h lth from spillage, although unproved, is regarded a a possibility not to be ruled out, and is to be the s ject of further experiment. Absorption through t skin may not be as important as was supposed, f it has been shown that a monkey may be anointed 70 times with ethyl petrol, at intervals of about a d y, without more than the merest trace of lead b ng found in its tissues after death. The Com- m ttee has been especially impressed by the reassuring f t that garage workers in the U.S.A. who have been h dling ethyl petrol continuously for four to five y rs show no signs of lead poisoning. Although s isfied on this point the Committee emphasises the v rning that ethyl petrol should be used only as a m tor fuel and not for such purposes as cooking or c aning. Sales in this country are, in fact, governed b regulations which require the dyeing of the s bstance red as an additional check against its use o herwise than as motor fuel, the labelling of cans and p mps, and the issue of notices to the public. The Departmental Committee has thus reported definitely o the main point at issue, although, as has been s d, further investigations are to be made on certain p nts. In the meantime, the city of New York h s just rescinded its prohibition on the sale of ethyl p rol within its borders.

THE M.A.B. ANNUAL REPORT.

THE Metropolitan Asylums Board has just published i annual report [1] for the year 1927–28, being the t rtieth year of issue. It is the familiar orange p per-covered volume of 350 pages, containing first a account in 75 pages of the Board's multifarious a tivities intended for the enlightenment of the p blic, then a number of elaborate financial and other t bles, and, thirdly, a series of monographs on one a ject or another of the clinical work done under the a spices of the Board. For those who have the i genuity and patience to find their way about this r port, it is a veritable mine of information. There m y still be readers who need to be reminded of the e ormous scope of the Board's activities, dealing a it does with the reception and care of various c sses of sick and infirm from all the unions and p rishes in London. The number of occupied beds i the various institutions of the Board on the last d y of the year under review was 20,746, and the t tal accommodation includes 8444 beds for fevers (i cluding 60 for ophthalmia neonatorum and 52 f r venereal diseases), 2168 beds for tuberculosis, 2 06 beds in children's institutions, 9387 beds in mental h spitals (not including 355 for sane epileptics), a d, finally, 734 beds in the training ship *Exmouth*, a d 828 beds in casualty wards for the poor. The t tal annual expenditure was round about £2,350,000, a otted to the four main groups—feeble-minded, f vers, tuberculosis, and children—in the proportions r ughly of 63 : 96 : 26 : 25. During the year the f ver accommodation has been revised and reallotted t conform with the standard laid down by the M nister of Health—viz., 1872 cubic feet, 144 square f et, and 12 linear feet per bed, without substantial d minution in the number of beds. In these hospitals a salutory change of policy resulted in the allocation o 1581 beds to measles at the beginning of April 1st. Although the daily average for diphtheria d ring the six winter months was as high as 2483, n t many scarlet fever patients were displaced, owing t the use of the Joyce Green Hospital at Dartford a a safety-valve. The concentration of cases of p erperal fever in two of the infectious hospitals, o e on either side of the river, has facilitated a research b Mr. J. M. Wyatt, the obstetric consultant, into t e method of infection in puerperal women ; in each case, when a patient is sent in, a swab is taken by the accoucheur from the throat of the nurse or midwife in attendance on the woman. At the Western Hospital a small number of beds has been allocated, as before, to cases of poliomyelitis in the acute stage, under the supervision of Mr. George Perkins. At the North-Western Hospital a clinic was opened last June for the treatment by radium of cancer of the uterus under the supervision of Mr. Comyns Berkeley ; the allotment of eight beds will suffice for the full use of two sets of radium applicators. The experiment of assembling cases of encephalitis lethargica at the Northern Convalescent Hospital, Winchmore Hill, has been continued, admission of extra-metropolitan cases having been sanctioned in order fully to utilise the allotted beds. This experimental unit, as Dr. G. A. Borthwick frankly admits, has not been productive of curative results, although it has proved valuable as an observation station, and on this ground the Board has approved its continuance. Artificial sunlight treatment has now been installed at four hospitals, two on each side of the Thames. Long Reach Hospital being under reconstruction, in May last cases of small-pox overflowed from the temporary accommodation loaned by the Willesden U.D.C. at Kingsbury, into the large reserve hospital at Joyce Green. The type of small-pox case in London now approximates closely to that which has prevailed for several years in the northern counties. In the first half of the present year 172 cases were admitted from 17 different metropolitan boroughs. During the year 437 students (of whom 79 were women) attended courses of instruction at the Board's fever hospitals. At the mental hospitals a revised dietary came into force in June, admitting of the use of fresh fruit, when obtainable, on two days a week, while a canteen for the use of patients has been established at Darenth Training Colony. A difficult situation is arising from the steady increase in the number of young able-bodied men seeking admission to casualty wards, and the Board proposes to reinstate the breaking of stone by hand as a deterrent task. No more has here been attempted than a brief outline of the Board's activities ; we shall have occasion to return to some of the clinical reports.

[1] From the Office of the Board, Victoria Embankment, ondon, E.C. 5*s*. The medical portion of the volume is tainable in four separate sections, price 1*s*. each.

CONTRIBUTORS to the Ferrier Memorial Fund met on July 18th under the chairmanship of Sir Charles Sherrington, and resolved to invite the Royal Society to accept the sum of £1000 in trust to found a David Ferrier Memorial Lecture. The balance of the fund will be applied as seems most suitable when the total contributions are known. The Fund is to be closed on Sept. 30th.

EPSOM COLLEGE—Founders' Day was observed at Epsom College on Saturday last, July 28th, when the celebration included service in chapel, distribution of prizes, and a garden party on the College playing-fields, where many parents and supporters of the College were spectators of a well fought-out cricket match between the College and the old boys. After service in chapel, and a luncheon-party at which the Council of the College acted as hosts, an adjournment was made to the big school-room to hear the headmaster's report, after which the prizes were distributed by Lord Riddell. The headmaster, Mr. Arnold Powell, was able to point to a year of successful work and successful play, the number of leaving certificates obtained being large, while the successes recorded in scholarship competitions and public examinations were numerous. Further, during the year the old Epsomians had, he said, given a good account of themselves, and this was indicated by tripos lists at Oxford, Cambridge, and London Universities, and by the pass-lists of various corporations and medical schools, the Law Society, and the Institute of Actuaries. Lord Riddell then distributed the prizes and delivered a short address in which he interested and amused the audience by a character sketch of Hippocrates, whom he held up for the imitation of youth as a fine example of independent thinking, high purpose, and power of mental concentration. During the afternoon the band of the 1st Battalion of the King's Own played appropriate selections, while in the evening a choral performance of *Iolanthe* was given by the College Musical Society. The organisation of the celebrations was excellent.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT CARDIFF.

REPRESENTATIVE MEETING: JULY 21ST-24TH.

(*Continued from p. 196.*)

Lunacy Law Reform.

Dr. R. L. LANGDON-DOWN, Chairman of the Committee on Lunacy Law and Mental Disorder, introduced the Council's memorandum on the Report of the Royal Commission published in 1926. He said that the Council did not regard as satisfactory the proposal that mental patients should be classified as "voluntary" and "involuntary." The Commissioners recommended that those who entered a mental institution on their own initiative should be termed voluntary patients whilst all the others were to be placed under compulsory treatment only after medical examination and on the order of a magistrate. Thus the proposed Provisional Treatment Order, except in the case of the voluntary boarder, involved the intervention of a legal official at the outset for every patient who required institutional treatment. This was by no means desirable, as the memorandum pointed out; in fact, if the early treatment of mental disorders was to be realised, legal intervention should be limited to cases in which the patient, *though capable of volition*, definitely refused and resisted institutional treatment. There were numerous patients in whom the will was in abeyance; many of these made an early recovery, and they ought if possible to be saved from the stigma of certification. The Council thought that they should be admitted to appropriate institutions on an "authorisation for treatment" given by a relative or friend and supported by the recommendation of two practitioners. On such terms it would be possible to get relatively early treatment, whereas the Commission's plan, by continuing in this respect the formalities of the existing law, would discourage a patient's relatives from taking steps in good time. The intervention of a justice was the great deterrent to early treatment at the present time.

Dr. DAVID ROXBURGH, for Marylebone, proposed that the report be referred back for further consideration on the ground that the Council had not "taken steps to promote legislation which would protect the certifying practitioner from vexatious litigation." There was, he said, a sword hanging over the head of anyone signing a certificate of insanity, and it must somehow be removed. Sir Frederick Willis, the late Chairman of the Board of Control, had stated in the press that the Board had for ten years been making strenuous efforts to get the law of lunacy altered, but public apathy had always resulted in measures of reform being crowded out of Parliament. As a powerful body like the Board had failed in all this long time to get anything done, the only thing left to the profession was to frighten the public into taking an interest in the subject. This could be done if medical men as a body would threaten not to continue the certification of the insane, and to do this would be a public service.

Dr. Roxburgh's motion to refer the report back to the Council was lost.

Dr. TEMPLE GREY did not approve of the Commissioners' statement, quoted in the memorandum, that "insanity is, after all, only a disease, like other diseases. . . ." This was not true from the point of view of diagnosis—the point of view of the general practitioner. In cases where the judicial authority intervened to secure detention in the public interest for persons of unsound mind, that authority ought, he considered, to accept responsibility for such detention.—Dr. LANGDON-DOWN said that proposals of this kind lost sight of the other functions performed by doctors under the Lunacy Act. A magistrate could not take over a medical man's whole responsibility, since the latter would always be liable to an action for lack of care in making out the certificate. It would be wholly unsatisfactory, indeed, if doctor were released from the duty of taking car To this Dr. GREY replied that absolution from duty of care did not mean the right to be care He thought that a magistrate should always be ca in if the patient proved resistant, and in the c paratively small proportion of cases where happened, the law should accept the responsibi After some further discussion this view was acce by the meeting, which passed the following resolut to be added as a rider to the Council's report:—

That the Representative Body, whilst thanking Lunacy Law and Mental Disorder Committee for Memorandum, considers that further protection for certifying medical practitioner is required; that is to that the judicial authority when it intervenes shall ac responsibility for the detention of persons of unsc mind.

Dr. W. JOHNSON SMYTH and Dr. E. K. LE FLEM for Bournemouth, put forward another amendn to the original motion accepting the memorand This ran as follows:—

That if, under Sections 13 and 16 of the Lunacy Act, 1 a magistrate make an order to one or two medical me the case may be (two medical men under Section 13 one under Section 16) to examine a person believed t of unsound mind, it should be considered that the magist should be solely responsible as an instrument of the and the doctors should have the status of a witness enjoy the immunities of a witness.

Dr. GREY had previously pointed out that words "status of a witness" could not be applie the circumstances; properly speaking, no one b witness could have the status of a witness. Bournemouth amendment was, however, carried, a references to Section 16 had been deleted.

Conflicting Medical Evidence in the Courts.

Dr. R. G. GORDON, for Bath, drew attention to Assize Court's decision in the case of Tyndall *v.* Alc Heavy damages had been given against Mr. Alc largely on evidence which seemed to be wise after event, and on appeal the judge had said in so m words that if the original decision had been in hands of himself and his colleagues, the result w no doubt have been different. As no new facts emerged he was, however, unable to reverse opinion of the jury. Dr. Gordon invited the Re sentative Body to say that it regarded the case consternation since it "would seem to expose surgeon who, although operating in good faith with due precautions, failed to obtain a perfect re from his operation to be found in damages by a of laymen." It was, he said, impossible to ex that the jury system would be altered, but a cer amount of abuse was creeping into the practic giving medical evidence in the law courts, and it desirable that the question should be ventila Possibly a medical assessor—an "impartial person ought to sit with the judge to help him in the weig of technical evidence. On behalf of Bath he posed that the Council should consider "whe means cannot be found to ensure that expert witne appearing on opposite sides in a case shall no confuse the issue by a divergent representatio facts that a lay jury cannot assess these facts at t true value."

The meeting asked Mr. O. Hempson, the As tion's solicitor, to express an opinion on this prop and he thought that, if passed, it might well quoted against members of the profession in c of alleged negligence. It would always be poss for litigants to obtain the services of a certain c of medical man, and the weight of such witne opinions would be increased if they could be re sented as men who had courage enough to put interests of truth before those of their profess Mr. Hempson believed that it would be a great take to pass a resolution suggesting that the B.M deplored medical men giving evidence against other.

Dr. Gordon consented to withdraw his motion

"An Infernal Machine."

The fact that England may still play some part in sh affairs was brought home to the meeting by . J. C. LOUGHRIDGE and Dr. J. R. GILLESPIE, from ose speeches it appeared that Belfast Corporation, the course of departmental reforms, had introced a system of "clocking in and out." To this ignity even the medical officers were asked to mit, and one of them, rather than do so, had ontinently resigned. They felt very keenly about s in Ireland, and they invited the Representative dy to say that it objected to medical officers eing required to record the time of their arrival or departure from, duty on a recording machine, it is derogatory to the dignity of the profession." ere was all the difference between signing one's me in a book and using an infernal machine; the ond method implied disbelief in one's honour. e B.M.A. had no more loyal adherents than in rthern Ireland (statistics of membership were here oted), and "God help us," said Dr. Gillespie, "if can't have the help of this mighty organisation." They got it, the motion being carried with no sentient voice.

Public Health and Poor-law.

Several resolutions introduced by Dr. E. LEWYS-LOYD, Chairman of the Public Health Committee, re carried without much discussion. The first laid wn that all tuberculosis officers whose clinical work areas is not subject to detailed supervision by the ef tuberculosis officer should be entitled to a nimal commencing salary of £750 per annum. e second dealt with pathological reports, and ran follows:—

That the work of laboratories established by public lth authorities should, in the opinion of the Representative Body, neither provide for pathological examinas nor furnish reports on individual cases, except (1) in es which directly involve questions of public health, or (2) where provision is made for such reports by statutory nt, or (3) when the patient is stated by the practitioner be unable to pay a fee; provided that in parts of the ntry where facilities for pathological examinations and orts are not afforded either by private practitioners thologists) or by the service of the local hospital, the blic health laboratory may properly make examinations a furnish reports as these are required by practitioners f patients who are in a position to pay the usual fessional fees.

The meeting agreed that in areas where there a cases of small-pox, and where propaganda work in avour of vaccination is not carried out by the local thority, the local division should try to stimulate t authority to do this work or else do what it can t supply the deficiency.

Another resolution, described by one representative a the "anchor of the general practitioner's freedom," n de clear the Association's policy that "domiciliary a endance should, in the best interests of the patients, b provided by private practitioners in the area con-c ned, and not by a whole-time medical officer." This was not to prejudice the position of any medical o cers at present holding whole-time appointments i which domiciliary attendance was one of the d ies, nor would it, of course, apply in areas where n general practitioner was willing to undertake the w rk on suitable terms.

The question of the combination of the duties of n dical officers, poor-law medical officers, and public v cinators was discussed in the light of probable c nges in poor-law administration. Dr. H. B. LACKENBURY, Chairman of Council, explained that t combination of these offices was now approved b the Minister of Health, and Dr. MILBANK SMITH s d that when the poor-law was abolished, it must b ensured that vaccination work was not transferred t the medical officer of health. The rights of the p vate practitioner must be safeguarded. The n eting agreed that there was no objection in principle t the combination in one and the same whole-time a pointment of (*a*) the duties of a M.O.H. and those o a poor-law institutional medical officer, or (*b*) the duties of an M.O.H. or poor-law institutional officer and those of a public vaccinator. But the application of these principles in any individual instance "must be governed by local circumstances and by the opinion of the Division or Divisions concerned."

Spa Treatment of Panel Patients.

Dr. H. G. DAIN, Chairman of the Insurance Acts Committee, introduced a scheme drawn up by the British Spa Federation for the provision of treatment for insured persons at various British spas. He said that the approved societies were not yet in a position to provide this form of additional benefit, but they might be able to do so out of their "disposable surpluses" after the next valuation. Meanwhile the Federation wished to be ready, and their scheme need cause no anxiety to the private practitioner, since all it demanded from him was the filling-up of a simple form of recommendation.

Criticisms were nevertheless raised from various points of view. Dr. A. T. JONES, for North Glamorgan and Brecknock, wanted to know exactly what was the position of private practitioners in the towns to which the cases would be sent. What was the definition of the "spa physician" by whom the cases would be treated? He wanted an assurance that the care of these patients would not be the prerogative of a few.—Dr. H. M. RAVEN (Broadstairs) thought that the fee of a guinea given to the spa physician for three weeks' treatment, exclusive of radiographic and bacteriological investigations, compared favourably with the fee of "about a shilling" which seaside practitioners got for three months' temporary residence by an insured person in their area.—Dr. L. W. BATTEN suggested that the spa physician's privileges were better defined than his duties.

Dr. E. R. FOTHERGILL, who had helped to draw up the scheme, agreed that participation in the treatment ought to be open to all those who had good credentials, and should certainly not be reserved for members of hospital staffs. Dr. DAIN cleared up the position by quoting certain criteria of a specialist—namely, that he should satisfy one or more of the following conditions:—

1. That he holds or has held hospital or other appointments affording special opportunities for acquiring special skill and experience of the kind required for the performance of the service to be rendered, and has had actual recent practice in performing the service to be rendered or services of a similar character; (2) that he has had special academic or post-graduate study of a subject which comprises the service to be rendered, and has had actual recent practice as aforesaid; or (3) that he is generally recognised by other practitioners in the area as having special proficiency and experience in a subject which comprises the service to be rendered.

This definition was accepted by the meeting, and Dr. JONES was assured that it did not preclude panel practitioners from being recognised as suitable persons to give treatment of the kind contemplated. Dr. E. SOLLY (Harrogate) said that there was now a very strong movement towards the provision of so-called spa treatment for insured persons, and on no account must this treatment be given by persons with no special experience.—Dr. F. G. THOMSON (Bath) explained what services the spa physician would render, and after Dr. DAIN had summed up the case in its favour, the scheme was approved with only two or three dissentients.

What is a Spa?

An entertaining discussion arose on an attempt by the Council to define spa treatment as "treatment at a place possessing a supply of natural mineral waters of reputed therapeutic value with facilities for their application. This implies the existence of suitable buildings, apparatus and trained personnel for work in bathhouses and other physiotherapeutic departments." Dr. E. WARD, for Torquay, moved that the word "mineral" should be deleted so that the definition might include sea-water, and this

proposal was warmly seconded by Dr. JOHNSON SMYTH, of Bournemouth, who also drew attention to the excellent facilities provided for the treatment of rheumatism at certain seaside resorts.—Dr. BRACKENBURY protested vigorously against this tampering with the definition. It would mean, he said, that nearly every town and village round the coasts of the Empire could claim to be a spa—and most of those inland as well. But the claims of seaside watering-places had made a strong impression, and Torquay's amendment was carried. A proposal by Mr. BISHOP HARMAN to destroy its general effect by inserting the word "approved" before "water" was rejected with ignominy, but Dr. BRACKENBURY eventually managed to persuade the representatives that the amended version was unsatisfactory, and the definition was referred back to the Council for further consideration.

Contract Rate for Juvenile Oddfellows.

A lively debate arose on the Council's decision that a standard rate of 8*s*. 8*d*. per head per year, including drugs, was acceptable for medical attendance on juvenile members of the Manchester Unity of the Independent Order of Oddfellows. This body has found its numbers diminishing through insufficient entries into the juvenile lodges. Failure of recruiting has been due to medical benefit being no longer given in many areas because it costs too much, and the Manchester Oddfellows have approached the B.M.A. to see whether such benefit cannot be provided at an economic rate. The policy of the Association has been that the same fee should be paid as under the National Health Insurance Acts—namely, 9*s*. plus 2*s*. 3*d*. or thereabouts, including medicine—but this policy, Dr. BONE reported, has been more honoured in the breach than the observance. There were few areas, he said, where anything like a capitation fee of 8*s*. 8*d*. had been obtained for dependants of the classes insured under the Health Insurance Acts, and the Council thought that it was a fair fee for the particular work to be done. There were in the Society 151,000 juvenile members, and the capitation fee at present being paid on their behalf was between 6*s*. and 7*s*. The profession would gain some £20,000 by a uniform rate of 8*s*. 8*d*., and in comparing this rate with fees received in the public medical service it must be remembered that there would be no deduction for the costs of collection and expenses generally, and that the service given would be relatively restricted as the children were under 16 years of age and needed less attention. Dr. BRACKENBURY said that the advantage of getting rid of records, of the need of certification, and of the disciplinary machinery was more than equivalent to any drug fees the practitioner would get if he had to provide the patients with medicine. He thought that 8*s*. 8*d*. was at least equal to the fee now being received under the Insurance Act.

This view was challenged by several representatives, whilst others maintained that 13*s*. per head per annum could be secured in many areas. Some pointed out that children should receive more and not less attention than adults. Dr. LEWIS LILLEY, for Leicester and Rutland, moved that the standard rate be approved "always provided that in any area in which a higher rate at present is paid this rate shall be allowed to stand, due regard being given to the special conditions and scope of service rendered in such area." But this amendment was lost, and the meeting finally approved the Council's resolution by a majority of 81 to 63. This resolution not only agreed to the standard rate of 8*s*. 8*d*., but also authorised the Council to approve a slightly lower rate in areas where, owing to economic conditions, the standard rate was not feasible. It laid down "that it be an essential part of this arrangement that there must be free choice of doctor by patient and of patient by doctor."

As the vote did not show the necessary two-thirds majority in favour of the resolution, it will not become part of the policy of the Association.

Coördination of Hospitals.

The Council having approved a memorandum presentation to the Minister of Health, this introduced to the Representative Body by McADAM ECCLES, Chairman of the Hospitals C mittee. It outlines a scheme based on the assump that poor-law hospitals will shortly come under control of county and borough councils. The step in coördinating their work with that of voluntary hospitals must, in the Council's opin be the establishment of a central advisory autho appointed by the Ministry of Health. This "cen consultative hospitals council" should map out country into areas—each served by an "coördinating hospital committee"—containing voluntary and municipal hospitals. These w again be subdivided and, as suggested in the Inte Report of the Consultative Council on Medical Allied Services, 1920 (the Dawson Report), all hospitals in a given district would be grouped ro a central or base hospital—generally one of bigger voluntary hospitals. This would be expe to set the standard of hospital practice and be chief centre of education and research. As "area coördinating hospital committees" w generally cover districts too large for administra control, each group of hospitals would work u the direct advice—and in some respects adm tration—of a group hospital committee. A pu hospital, when not itself the central or base hosp should develop in coöperation and not in competi with the voluntary hospital. The responsibility treatment in public hospitals could be underta by a visiting medical staff (on a part-time b with the assistance of a resident medical staff; practitioners treating patients for whom the Gov ment or local authorities are responsible, sh receive either an honorarium or a fixed salary definite services and responsibility.

A proposal to refer the memorandum back the Council for further consideration was m from different points of view by Dr. E. W Masterman, for Camberwell, and by Dr. Gra Little, M.P.

Dr. MASTERMAN said that this was a consulta scheme. In the opinion of all the medical sup tendents of poor-law institutions it was "impossil and it would wreck all attempts at coöperation helpfulness. He was all in favour of the volun system, but if the voluntary hospitals kept ou the State service they could not expect quite same consideration as if they were in it. In scheme, the base hospital should logically be State hospital, because this was obliged to take patient requiring treatment, whereas the volun hospitals, especially those with students, were ob to select their cases. He did not believe, how that it was wise to put any hospital in a primar superior position in a district. Nor could he app the suggestion that in public hospitals responsib for treatment should be taken by the visiting s In public health hospitals at the present time t was a whole-time regular staff and consultants only called in when necessary.

Dr. GRAHAM LITTLE pointed out that the Da Report had been published eight years ago whe situation of the voluntary hospitals was despe Now 75 per cent. of those in the provinces, an per cent. of those in London, had balances at banks. It was dangerous to give this openin the Ministry of Health for controlling the volun hospitals, and it would be very regrettable if policy of the Association were to weaken the volun system.

Dr. M. W. RENTON (Stratford) complained the threshold of the voluntary hospitals was often closed to general practitioners. There w mistaken idea that the whole of the work shoul done by consultants.—Mr. BISHOP HARMAN trasted the views of Dr. Masterman and Dr. L in their opposition to the scheme. It would

possible to please both parties.—Dr. TEMPLE GREY ged postponement. He did not like the suggestion at the central consultative council should be set by the Ministry of Health.—Mr. H. S. SOUTTAR, wever, said that if the Association's decision was be of any value it must be sent to the Minister at ce. It was surely obvious that there must be ne consultative body to coördinate hospital rk. The object of having base hospitals was to e waste of time and energy; they were not going take "good" cases, but were going to set an ample of what could be done, and were going to p others in every possible way. Whilst it was the ty of public hospitals to take all and sundry tients, it was the duty of voluntary hospitals to pply the highest possible level of medical service, provide education for medical men, and so far as ssible to assist the public services.

Dr. C. E. S. FLEMMING saw no reason to fear that State would want to control voluntary hospitals. en State aid would not necessarily mean State erference.—Sir RICHARD LUCE, M.P., said that rdination would be impossible without the inter- ntion of some outside body, representing the erests of all concerned. Cottage hospitals, fever spitals, and the rest would look to the base hospitals a educational centres, and they would be a very portant element in post-graduate work.—Dr. THERGILL was much more frightened of State spitals than of voluntary hospitals, the majority which in this country were staffed by general ctitioners.—Dr. R. C. BUIST, speaking as a member the Voluntary Hospitals Commission, said he d signed with a heavy heart that section of Commission's report which dealt with financial istance of the voluntary hospitals from mass tributions. When the poor-law hospital became nicipal and lost its stigma, it would inevitably ne into competition with the voluntary hos- al, and if its service was adequate it would n sooner or later. People who provided treat- nt for themselves by paying rates would entually drop out of contributory schemes.—I. A. B. MURRAY pointed out that already very few spitals were truly voluntary; their work on venereal eases, child welfare, ophthalmia neonatorum, and other directions was State-aided. Whereas in hospitals the voluntary staffs, in giving their vices, were only casting bread upon the waters, ctitioners who joined the staffs of small country spitals did their work for nothing and got no irect return. Much of this work should be paid —a suggestion which had found no place in the morandum.

While summing up in favour of referring back the morandum to the Council, Dr. MASTERMAN said t in his Division there were 2400 beds belonging public authorities, and no voluntary hospitals. ery practitioner was welcome to come in, examine, l talk over his case. He visualised, in the future, annexe in State hospitals where practitioners ld definitely undertake the treatment of their n patients.

The amendment being lost by a large majority, the eting approved the Council's memorandum. ther discussion took place on the criteria for ctitioners treating private patients in private rds or nursing homes attached to hospitals, but s question was referred for further consideration

Other Subjects Discussed.

The following motion by Edinburgh and Leith s approved without discussion:—

(1) That in the interest of the public health the British dical Association support any measures which may be en so to alter or amend existing legislation as to give ater power to local authorities to suppress unnecessary se which is disturbing to the lieges; and (2) that any se from 11 P.M. to 6 A.M. which is capable of being vented or mitigated and which is dangerous or injurious health, shall be a nuisance within the meaning of the blic Health Acts.

A resolution passed in 1926, saying that in accident cases treated at a voluntary hospital, where medical attendance is covered directly or indirectly by insurance, "the hospital authorities should recover from the insurance company the full cost of maintenance and treatment," was amended by deletion of the words "from the insurance company."—Buckinghamshire carried a motion asking the Council to consider whether some arrangement could be made for pay ment for the emergency services rendered by doctors to patients meeting with accidents on the roads.

In introducing the report of the Naval and Military Committee, Dr. F. W. GOODBODY, the chairman, advised that careful inquiries should be made at the present time before advising medical men to enter the Indian Medical Service.

Dr. C. L. LEIPOLDT, Secretary of the British Medical Association in South Africa, referred to the need for improving post-graduate education in England. Practitioners from the Dominions regarded themselves not as students but as the equals of any practitioner in this country. They therefore did not appreciate the instructive methods of specialists at the big teaching hospitals in this country.

At the end of the meeting a cordial vote of thanks was passed to Dr. Hawthorne for presiding, and to other officials who had worked for the comfort and convenience of the meeting.

THE ANNUAL MEETING.

At the annual meeting at the City Hall on July 24th the outgoing President, Sir Robert Philip, handed the insignia of office to his successor, Sir Ewen Maclean. The President-elect, Prof. A. H. Burgess, was introduced to the assembly. At the adjourned annual meeting, held at the New Theatre on the evening of the same day, the new President delivered the address published in our last issue. The Sir Charles Hastings Clinical Prize was awarded to Dr. Ambrose Owen, the Stewart Prize to Sir Malcolm Watson, and the Katherine Bishop Harman Prize to Dr. Ronald Hare.

THE RELIGIOUS SERVICE.

At the official church service, held at St. John's Church on July 24th, the sermon was preached by the Rev. Garfield Williams, M.B., honorary Canon of St. Albans, who spoke on the character of St. Luke. Even yet, he said, the Church had not realised the importance of what might be described as the extra-professional activities of that travelling physician of the first century. He was the greatest biographer of our Lord, so far as pure biography was concerned; he was the first and greatest of Church historians, and he was the companion and guardian of Paul the missionary. He had the practical mind of the physician, and he thought out the ways and means whereby the visions of his companion Paul might be carried out into action. One side of his character to which the preacher drew attention was his interest in persons—in personal details, at all events those which were important. That was true of the physician always. He did not treat diseases, in spite of what the public might suppose; he treated persons.

THE ANNUAL DINNER.

More than 500 people attended the annual dinner of the Association, held at the City Hall on July 26th, when Sir Ewen Maclean presided, and the guests included the Lord Mayor and Lady Mayoress of Cardiff, the Marquis and Marchioness of Bute, the Archbishop of Cardiff, Dr. Franklin Martin (director-general of the American College of Surgeons), and Sir George Syme (president of the Federal Committee of the B.M.A. in Australia).

Proposing the health of the City of Cardiff, Mr. R. G. Hogarth said that, like many other visitors, he had imagined Cardiff as a city of smoke and ugliness; he found it endowed with civic buildings unrivalled in many a European capital. It was interesting to think of all these beautiful and

concordant buildings as an expression of the coal trade, now going through a time of trouble, and he trusted that the courage which had made Cardiff great would stand by her in the present difficulties. In his response the Lord Mayor said that they were all hoping that the day would come when Cardiff would be recognised as the capital of Wales, and they had already reserved a site for the National Parliament. Meanwhile Cardiff would appeal to the medical profession because it was a city without a slum. There was not one house in it that the Ministry of Health would condemn.—Dr. H. B. Brackenbury replied to the health of the British Medical Association, proposed by Sir William Seager, and Dr. C. O. Hawthorne, giving the health of the guests, coupled the toast with the names of Sir William Diamond (chairman of the Board of Management of the Cardiff Royal Infirmary) and of Sir George Syme, both of whom responded.—Dr. W. E. Thomas wittily proposed the health of the President, Sir Ewen Maclean, who was, he said, the first ex-chairman of the Representative Body to rise to this high office.—After this health had been drunk with musical honours, and Sir Ewen had replied, the proceedings ended with the National Anthem.

THE SOCIAL SIDE.

The principal building of Cardiff is the Castle, owned by the Marquis of Bute, which comprises a large Roman fort, a Norman keep, and residential buildings belonging to nearly every English architectural period. The grounds extend for several miles towards Llandaff and the part now called Cathays Park has been made over to the city as a site for national and municipal buildings. These include the Law Courts, the County Hall, the Technical College, the Welsh National Museum, the University College of South Wales and Monmouthshire, and the City Hall. In the centre lies the National War Memorial, and the whole group of buildings, constructed in Portland stone and separated by open spaces and wide avenues, is unlike anything to be seen elsewhere in this country.

The scientific sections met at University College and in the Technical College, but most of the social functions, and the Representative meeting, were held in the City Hall. On Tuesday evening the Hall was used for a reception by the President and local executive, and on this occasion a birthday present was given by the Association to the Earl of Dumfries, Lord Bute's eldest son, who was celebrating his coming-of-age. On the following evening the Hall was again used for a reception and dance, the host this time being the Lord Mayor.

On Wednesday afternoon there was a reception at the Cardiff Royal Infirmary; on Thursday Lord and Lady Bute entertained some 6000 guests in the Castle grounds; and on Friday evening the National Museum, at an official reception, displayed its many beautiful treasures, together with a special collection illustrating the history of Welsh medicine.

On Sunday the Representative Body enjoyed an excursion to St. Donat's Castle, where a religious service was held in the courtyard. Before setting out the Representatives attended at the National War Memorial, where the President-elect laid a wreath on behalf of the Association. Many expeditions to places in the locality, including the Docks and the Bargoed Colliery, were arranged during the subsequent week.

The Popular Lecture was given at the New Theatre on Friday evening by Sir Berkeley Moynihan, who spoke on Art in Medicine, and on Friday the honorary degree of Doctor of Laws was conferred by the University of Wales on Sir Robert Philip, Dr. H. B. Brackenbury, Dr. W. W. Chipman (Professor of Obstetrics at McGill University), Sir Thomas Lewis, Dr. Franklin Martin, and Sir George Syme.

THE ANNUAL EXHIBITION.

An account of the exhibition, which was formally opened on Tuesday by Sir Ewen Maclean, will appear in a forthcoming issue of THE LANCET.

SECTION OF MEDICINE.

Sir THOMAS LEWIS, who presided at a discussion

DISEASES OF THE CORONARY ARTERIES,

remarked that the dictum, "a man was as old as arteries," contained a considerable element of tru especially if it was applied to the cerebral, renal, a cardiac vessels. The coronary arteries had be the subject of discussion on several occasions these meetings as well as elsewhere, but many proble concerning them were still wrapped in obscuri Disease of the coronaries always interested medi men, for many notable physicians had been affect by it. John Hunter, and in modern times Sir Jam Mackenzie, were two out of many examples. T western counties had a peculiar interest in the c dition, for the earliest and some of the most importa observations on coronary vessels had originated the 160 years ago Heberden gave the first clear descr tion of coronary disease. Its connexion w angina pectoris was first pointed out to Edwa Jenner by a surgeon living in Ross, who did a po mortem on a case of angina and noted disease the coronary arteries. Jenner wrote his opin on this to Heberden in a private letter, but his vie were never published, out of consideration to friend, John Hunter. There had been great advan in recent years, in two directions especially. T first was in the study of the anatomy of the vess of the heart and their anastomoses in heart muso The second was the precise study of the sympto and signs of coronary thrombosis. This was bou to throw light on our knowledge of angina pecto

Dr. GEORGE A. ALLAN (Glasgow) began his open address by defining the limits of the discussi Speakers must beware of detracting from the va of the main subject by excursions into theories angina pectoris. Nor must they narrow the outl by concentrating on one aspect alone of coron disease, such as coronary artery thrombosis. then surveyed some of the essential features of t subject.

The association of special symptoms with occlus of the coronary blood-supply had been recogni since 1878, but only in the last few years had a cl distinction been established between it and the m widely recognised syndrome of angina pectoris. V important anatomical investigations had been ma by Gross and his collaborators, who concluded t the heart was perhaps the richest organ in capill and precapillary anastomoses. From the morl anatomy point of view there were four clearly defi diseased conditions of the coronary arteri atheroma, arterio-sclerosis, syphilis, and calcare degenerations. These terms were often so loos used that it was necessary to define them. Atheron the commonest primary lesion in the coronaries, ha patchy distribution. It was the same disease atheroma of the aorta and had the same tende towards ulceration and thrombosis though in a l degree. Atheroma was very irregular in its dis bution in different vessels. The coronaries a other deep arteries might be affected, while superficial arteries might give no indication of presence. Arterio-sclerosis was a more diffuse proc characterised by thickening of the media and intin It was the same as arterio-sclerosis associated w high blood pressure and might, or might not, ca narrowing of the vessel. Syphilis, though comm in the aorta, was rare in the coronaries. They we however, liable to be occluded at their point of ori by syphilitic mesaortitis. Calcification might superimposed on either atheroma or arterio-sclero or might occur as a primary medial degenerati The deformity it produced in association w atheroma frequently caused narrowing of the lum with or without thrombosis.

With regard to the relative frequency of t conditions, the speaker found that out of 1000 po mortems at the Western Infirmary, Glasgow, corona artery disease was found in 371. Of these 238 show

efinite lesion of the myocardium—178 presented osis, 12 fibrosis and fatty change, and 48 fatty nge alone. Atheroma was the most frequent on and caused fibrosis in 51·2 per cent. of cases. ny of the cases illustrated the remarkable adaptaity of the anastomotic channels under favourable ditions. From this study, in addition to general rmation regarding frequency and effects of ons, three points emerged: (1) severe coronary rowing might be present without obvious lesion in myocardium; (2) old-standing severe arterial lesions actual occlusion with fibrosis might occur with no ical history pointing to it; (3) patients might die h symptoms suggesting coronary artery occlusion no such lesion be found. There was no diagnostic ptomatology which would cover all cases of nary disease. When the blockage was abrupt ain features were present. Hamman divided s into six classes: (1) sudden death; (2) death few hours; (3) continued myocardial insufficiency h death in weeks or months; (4) recovery after ve symptoms; (5) cases that were not grave but gnisable; (6) mild or uncertain cases. He would e symptomatology to other speakers. The gnosis was grave, but owing to difficulties in gnosing mild cases, the proportion of recoveries ld not be stated. In treatment they must disguish between treatment of the actual disease and tment of a complication, such as thrombosis, ing in the course of that disease. In thrombosis first indication was to relieve the pain. Morphine required, often in large doses. Digitalis was metimes of benefit. He himself had been impressed h the value of glucose in strengthening the heart, had not been able to follow a sufficiently large es of cases to speak dogmatically. He gave f a pound daily. Treatment of actual disease of coronary arteries resolved itself into prevention of h conditions as atheroma and arterio-sclerosis. s could not be efficient until their ætiology was ter known.

Ischæmia and Infarction.

Dr. CAREY F. COOMBS (Bristol) based his remarks cases seen as in-patients. He defined two chief nary syndromes, ischæmia and infarction. In sæmia there was substernal pain, excited by rtion and relieved by rest. In infarction the sternal pain was continuous. These groups were rly defined, although it was difficult to draw a line ween them, since a case of ischæmia might pass r into one of thrombosis. The age-incidence of sæmia and infarction corresponded fairly closely the highest peak of the curve for ischæmia urred about a decade earlier than that for infarcn. The reason for this was that ischæmia was erally due to syphilis, which caused nipping of the ice of the coronary arteries but rarely led to rction, whereas degenerative conditions, especially eroma, caused destruction of the intima and rction. With regard to sex-incidence, males ponderated to the extent of 71 per cent. in sæmia and 82 per cent. in infarction. Most of females in the ischæmic group had high arterial sion, but this was not so for the males. The effect heredity could not be statistically proved, as it difficult to get accurate family histories. The ients died at an advanced age (60–70), so that family history had been forgotten. Nevertheless, re was a decided family incidence; several examples e quoted.

he ætiology of coronary disease was graphically wn. Rheumatism and ulcerative endocarditis lom produced gross lesions, for although much nage to vessels was found microscopically, there s, as a rule, no interference with the blood-supply. y interesting were the infective group of cases, which the speaker had seen several examples urring about the age of 40 and often associated h phlebitis. Most of the cases were of the degenera- type and arose from circumstances over which y had little or no control. With regard to treatment, he had found caffeine and diuretin of value in patients who suffered from cardiac pain on slight provocation.

Dr. IVOR J. DAVIES (Cardiff) emphasised the importance of looking for arterio-sclerosis or atheroma in clinical examination of patients. Burns, in 1809, had compared the diseased heart to a limb round which a moderately tight ligature had been tied. Ordinary work could be carried out, but further exertion produced the symptoms of intermittent claudication. Intermittent claudication was the probable cause of the pain of coronary disease. True cardiac pain did not occur in valvular disease unless decompensation was also present. The character of the pain was important. It tended to be epigastric in coronary thrombosis, hence the liability to confusion with abdominal disease. Angor animi was pathognomonic of coronary disease and emotional stress was often an exciting cause of the pain. The speaker then gave an account of the symptoms and physical signs of thrombosis, laying special stress on restlessness, especially if it occurred in a patient already suffering from heart disease.

Diagnosis and Prognosis.

Dr. A. G. GIBSON (Oxford) dealt with diagnosis and prognosis. Coronary disease should be suspected in cases of: (1) serious pain in the chest; (2) acute cardiac failure with fainting attacks; (3) acute pain in the upper abdomen with an irregular heart. It was necessary to distinguish between angina and coronary disease. In the former the pain came on during exertion and lasted for minutes, dyspnœa was absent, and the blood pressure was normal or raised. In the latter the symptoms lasted hours or days; there was vomiting, abnormal pulse-rate, low blood pressure (especially low pulse pressure), and, later, fever and leucocytosis. In some cases there was acute cardiac failure with pallor, sweating, restlessness, and entire absence of pain. Fainting attacks in persons over 40 should be regarded with grave suspicion. The blood pressure, pulse-rate, and response to exertion should be watched. The distinction between coronary thrombosis and acute abdominal conditions might be difficult. If they occurred together it was better to operate, for the administration of an anæsthetic, although the risk was greater, did not present insuperable difficulties. Coronary disease might be suspected in chronic cardiac failure occurring in older people. But however careful they might be in diagnosis, there would be some cases impossible to identify during life. With regard to prognosis, figures did not help much until the different factors concerned in the condition could be separated. Patients who recovered from an attack of thrombosis might live many years even with extensive fibrosis of the heart muscle. Specimens of hearts from two such cases were shown.

Dr. JOHN S. CAMPBELL (Belfast) showed a series of X rays of hearts in which the coronary circulation had been injected with an opaque emulsion. Age changes were illustrated by a fœtal heart where the right and left ventricles received an equal blood-supply, the heart of a man of 50 showing decreased vascularity of the right ventricle, slightly tortuous arteries, and better developed anastomoses, and that of a man of 75 where these changes were much more marked. The next series dealt with anastomoses developing after coronary thrombosis. In one case of thrombosis of the right coronary and circumflex the whole of the arterial tree distal to the block had become filled with injection material through anastomoses with branches of the left coronary. Diagrams of variations in the areas supplied by the two coronaries were also shown.

Dr. D. EVAN BEDFORD (London) spoke of electrocardiographic changes and described the typical curves found in coronary thrombosis. Widening of the curves, splintering or notching of the waves, and low voltage were common in coronary disease. He showed electrocardiograms taken two days and four days after coronary thrombosis. Besides the above,

they were characterised by absence of the T-wave and a plateau following the R-wave in lead 2. A few weeks later there was a change. The T-wave was inverted in either lead 1 or lead 3, and was flattened in lead 2, but to a less degree. After 17 months in the case shown there was still inversion widening and notching, but the curve then began to change in the direction of the normal. Eventually normal curves were obtained. One great value of electrocardiograms was that they strengthened the physician's hand when he insisted on prolonged treatment after an attack. Patients often tried to work as soon as the acute stage had passed, and it was important to prevent this.

In the discussion which followed, Dr. BAIN said that coronary spasm had been advanced in France as the cause of cardiac pain. It was difficult to see how sclerosed arteries could go into spasm. He would like to ask, however, whether spasm could be the cause of angina without coronary disease.

Prof. T. G. MOORHEAD (Dublin) was interested in Dr. Coombs's infective group of cases in which angina was associated with phlebitis. He had published a case of thrombo-phlebitis migrans, in which phlebitis had begun in the leg, then attacked various regions of the body, and, finally, coronary thrombosis had occurred. The patient was now in good health.

Dr. A. R. GILCHRIST (Edinburgh) called attention to a group of cases in which angina was associated with paroxysmal tachycardia. He doubted whether as much could be deduced from electrocardiograms as was sometimes thought. He had one case which showed inversion of T-waves in several attacks and was diagnosed coronary thrombosis. Post mortem no occlusion of either coronary was found. The pain was probably due to paroxysms of tachycardia. Electrocardiographic records were seldom confirmed post mortem and often none had been taken before the attack.

Dr. DAVIES, in reply to Dr. Bain, said that coronary spasm was the probable cause of angina. It was doubtless the same lesion as the cerebral angiospastic attacks which caused transient hemiplegia. Alterations in cardiac rhythm were certainly due to thrombosis of the artery to the A.V. bundle.

Dr. BEDFORD said that it was dangerous to give a prognosis merely from the study of an electrocardiogram. An inverted T-wave could not be said to be of grave import, because it frequently became altered later. He considered low voltage the most serious sign. It was very difficult to obtain post-mortems on cases that had been followed electrographically and therefore there was no large series of such cases. In many of his cases, however, the diagnosis had been so confirmed.

Conclusion.

The PRESIDENT summed up the symptoms of coronary thrombosis and described the appearance of the heart in experimental lesions. With regard to prognosis, he agreed with several speakers who had said that the condition was not necessarily a very grave one where there was recovery from the initial attack. In giving a prognosis they had to consider the state of the coronary arteries. A review of the history and the condition of the patient after the event would help in this.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

AT its first session, under the chairmanship of Mr. T. WATTS EDEN, a discussion on the prevention and treatment of

UNSUCCESSFUL FORCEPS CASES

was opened by Dr. DOUGLAS MILLER (Edinburgh), who analysed a group of 558 cases delivered in Manchester, Glasgow, and Edinburgh. In 211, of whom 139 were primigravidæ, the underlying cause of dystocia was *disproportion*, due for the most part to pelvic contraction, and in a few to an abnormally large child. The flat rachitic type of pelvis was exceptionally common in Glasgow. In 14 deform of the outlet and in 6 a contraction ring prov an additional obstacle. Disproportion varied wi in degree; sometimes it had been difficult to ren the head even when crushed, sometimes labour w have been normal if forceps had been withheld. 161 patients the cause of difficulty had been a *post position of the occiput*, for the most part unrecogni This fact emphasised the urgent necessity of accu orientation of the head, for which purpose the ear a more reliable guide than sutures or fontanelles. most of these occipito-posterior cases the head been deeply engaged, with the occiput either in hollow of the sacrum or still obliquely poste In the large number, however, in which the head still high or movable at the pelvic brim, the soft p had been severely bruised and lacerated by slip forceps. In several cases the cervix had been partially dilated, and was badly torn; somet the tear involved the lower uterine segment.

In a third group of 151 cases *no abnormality* been present. Some of these might have occipito-posterior before their transit to hospital in a large number anxiety to relieve suffering obviously made the practitioner apply for before dilatation and head-moulding had sufficie advanced. The fourth group consisted of 12 cases.

Treatment.

Where disproportion was the cause, treat depended on its degree, the condition of the c and whether an adequate test of labour had made; 78 patients of the 211 had been deliv spontaneously or by low forceps. Craniotomy had employed in 98 cases and Cæsarean section on 12; 21 of the 29 maternal deaths had been du puerperal sepsis. Of the 161 cases due to occi posterior position the majority were advanced in second stage with the head arrested on the p floor, and an attempt had usually been mad rotate manually and complete delivery with for When impaction had prevented rotation, craniot had usually been performed. In two-thirds of instances in which the head had been arreste the inlet of the pelvis, or the upper part of the ca manual rotation of the head had been combined external rotation of the body. Where the os been found fully dilated, forceps had been immedi put on and delivery completed; when the c had not been completely effaced, labour had allowed to proceed. Internal version, perform a last resort in 11 of these cases, had saved thr the children.

In most of the 151 cases in which premature s cation had been the only cause of failure, the pa had been placed under morphine or twilight and delivered spontaneously or by low forceps. the child had been dead or dying, craniotomy been performed.

The total maternal mortality had been 5 10 per cent.; of these the cause had been sepsis uterine rupture 8, post-partum hæmorrhage shock 6, and pneumonia 3. In 132, or 23·6 per the puerperium had been morbid by the B standard; 357 children, or 64 per cent., had lost. Many of the patients had only left ho after exhausting weeks of fever, and many had to undergo further weeks or months of ill-health laceration of the cervix, vagina, or pelvic End-results in 98 patients who had been follow had been 24 complete recoveries and 74 re disabilities of varying degree, the most fre being laceration of the cervix, usually due to ap tion of forceps before dilatation. Backward dis ment of the uterus, usually associated with involution, downward displacement, and pelvic tion was common. Pelvic infection occurr one-third of the cases; 24 patients had had to un operation for their resulting disabilities.

Unsuccessful forceps cases resulted largely fro breach of three rules: forceps should never be a

when marked disparity existed between head and is, hardly ever when the head was still movable ve the pelvic brim; (2) without an exact know- e of the position of the head; (3) until the cervix completely effaced and retracted over the present- part. It would be a counsel of perfection to id the application of forceps except on strict cations, but greater care and discretion in their was a reasonable ideal.

The Importance of Antenatal Care.

rof. JAMES HENDRY (Glasgow) pointed out that lic interest in puerperal morbidity was thoroughly ised, and that there was no doubt whatever that doctor was held responsible. Dr. Miller had ided the records; he himself would attempt to ider to what extent more efficient antenatal would have prevented these accidents.

most of the cases of disproportion, contracted is and not an abnormally large child had been cause. This could nearly always have been tified in early pregnancy; skeletal irregularity an important danger-signal. Internal examination essential, and the form of the pelvic outlet should noted; a sharp subpubic angle with reduced ance between the tuberosities indicated contraction he outlet and might pass unnoticed until late in ur. Examination of the diagonal conjugate eter should always be attempted. It might difficult in the early months, but was usually ible during the seventh or eighth, especially if patient "bore down," relaxing the perineal cles. Short fingers were not really a handicap. fingers should also sweep round the pelvic brim etect asymmetrical deformity, a small transverse eter, or ovarian cysts or fibromyomata. Towards end of the pregnancy a pendulous abdomen in a igravida should arouse suspicion. If the head d to descend into the pelvic cavity during the month the cause might be faulty presentation, lasm, or even placenta prævia, but was often racted pelvis. The history of previous labours most valuable. X rays were not of much help, pt possibly in the generally contracted pelvis, n Prof. Martin's method was of value.[1] At this e the fœtal head was the best of all pelvimeters. method of election, that of Müller, should be rmed under an anæsthetic during the last month. ntracted pelvis, however, the position of the head d not indicate how it would mould or alter its tion in labour, and Munro Kerr's method of imetry gave a far more reliable prognosis. In ur, if forceps were decided on, a most careful amination should be made, if necessary with the l in the vagina, after the patient had been sthetised, and if great difficulty were then apparent use of forceps should be foregone. Rectal ination was safer than vaginal examination, just as satisfactory. In borderline cases, if ress were not satisfacory after a good long ur, the lower segment Cæsarean section should erformed.

cipito-posterior presentations were usually identi- e by careful antenatal examination. Where ation was difficult two X ray photographs, frontal lateral, should give a complete diagnosis. Dr. ltain had secured permanent correction by pads a binder in 87 per cent. of primigravidæ, and er cent. of multiparæ.[2] 60 per cent. rotated spon- ously, but it was important to recognise the ciation of this condition with protracted labour. as often accompanied also by slow dilatation of cervix. Other abnormal presentations, or the rmities which would cause them, were practically dentifiable before labour. Hydrocephalus was y detected, except when obscured by hydramnios, perforation might prevent an exhausting labour. ual dilatation of the cervix was seldom justified, even when attempted, was hardly ever complete.

[1] Zeitschr. f. Geburtsh. und Gynäkol., 1927, xci., 3, p. 504.
[2] Proc. Edin. Obstet. Soc., 1926, p. 133.

Antenatal examination of this kind could often be carried out by the general practitioner, but there was need for efficient consulting centres. The work was far too responsible and difficult for midwives, and no midwife should be authorised to undertake the care of a pregnant woman unless provision were made for careful examination by a medical practitioner before labour were due.

Prof. W. FLETCHER SHAW remarked on the large number of craniotomies in the series compared with Cæsarean sections, in spite of the increased use of the section by every obstetrical unit. Performed upon a "clean" patient its mortality was very low, but after attempts at forceps delivery it was highly dangerous. Many patients were badly lacerated, and others were shocked; some were definitely infected, and in some cases the child was dead or damaged. Pubiotomy had never become popular, and was only useful when a small amount of widening would make the difference between retention and expulsion. Miscalculation of the amount led to severe laceration.

The main reasons for failure in forceps delivery were professional and lay apathy. Obstetrical teaching was relegated to a subordinate position, and the public did not realise how difficult maternity cases were. Remuneration was poor, and the relatives looked down upon a doctor who called in expert assistance. It was necessary to educate the public and to provide more and sounder clinical teaching. Stress should be laid on four points: antenatal care, asepsis (Prof. Shaw condemned coal-tar derivatives), resistance to the relatives' importunity in the first stage of labour, and definite diagnosis before applying high forceps.

Discussion.

Dr. CHARLES DOUGLAS (St. Andrews) appealed to general practitioners to shoulder the responsibilities of antenatal work, and warmly recommended version as an effective stand-by when hospitals were far off, with the stringent proviso that the os should be fully dilated. Chloral was very valuable in securing dilatation. Even after forceps had failed, version would often safeguard future maternal efficiency.

Prof. BETHEL SOLOMONS (Master of the Rotunda Hospital, Dublin) put most unsuccessful forceps cases down either to abysmal ignorance or to wilful negligence. The first could be removed by training, especially on the management of the all-important first stage; the second should be punished by legal process. Failed cases should be distinguished from cases where forceps had been used tentatively with a view to later pubiotomy or lower segment Cæsarean section. The present curriculum was too short, and an extra year should be allotted to the post-graduate study of obstetrics. He deprecated Dr. Miller's classification of "children dead or dying on admission." It was impossible to tell whether a child was dying, and the impression that it was possible would lead to a far too free use of the cephalotribe. The man who had strength of mind to avoid forceps when contra-indicated, and strength of arm to deliver the head when they were indicated, would have no failed cases. In the Rotunda there had only been 10 in 6000 or 7000 deliveries.

Dr. MABEL RAMSAY (Plymouth) viewed craniotomy with horror, and recommended section, even after forceps had failed. Antenatal schemes broke down because the patient would not realise their value; moreover, the officers in charge were often inadequately trained.

Dr. F. EDGE (Birmingham) saw a solution in compulsory antenatal consultations with adequate remuneration.

Mr. L. C. RIVETT (London) urged four conditions for applying forceps: engagement of the head, full dilatation, passage of the greater diameter through the cervix, and an empty bladder. Neither version nor craniotomy should be performed when the liquor amnii had drained away and the uterus was in an

irritated condition; Cæsarean section was then much safer. A six months' course in obstetrics was the very minimum.

Dr. R. KELSON FORD (Preston) asked for expert opinion on instrumental version and the use of Kellan's forceps. In the municipal maternity home of which he had charge he had no difficulty in getting paying patients to attend for antenatal, but only about one in three came for postnatal examination. Antenatal inspection should be performed not later than the thirty-sixth week. The Association should insist that, in any future State-run maternity hospital, the private practitioner should be able to attend his own patients.

The Secretary, Mr. B. K. TENISON COLLINS (Cardiff), said that certain midwives recommended doctors for the rapidity of their deliveries, regardless of the result; practitioners were thus forced to use forceps against their better judgment. The remedy was an educative campaign.

Dr. KENNETH WILSON (Blandford) described a case of hydrocephalus, and one in which multiple fibromata had nearly caused a failed forceps case.

Dr. H. R. PARAMORE (Rugby) advocated pubiotomy, which he claimed was easy and gave good results, although the hæmorrhage and laceration it caused were somewhat alarming.

Dr. J. BOYD (Manchester) objected to Prof. Solomon's strictures on the ignorance and negligence of practitioners, and said that if the Master of the Rotunda had to work under the conditions of some general practitioners his results would compare unfavourably with theirs.

Dr. J. S. QUIN (Dublin) pointed out that a Master had to undergo a severe apprenticeship in some of the worst slums in the world. Students were not taught enough about normal labour, and when they might refrain from interfering. A quarter of a grain of morphia at the onset of labour might result in a good many births before arrival, but it saved much anxiety and, if always given, would wipe out failed forceps cases. If lysol were abolished a large number of deaths from sepsis would be avoided.

Replies.

Dr. MILLER, in reply to Prof. Solomons, said that by "dying" children were meant those in which fractures of the skull could be palpated. In some cases, moreover, when neither pubiotomy nor Cæsarean section were available, the claims of mother and child had to be balanced, and the mother's were, in his opinion, the weightier.

Prof. HENDRY said that proper care of the first stage should exclude contact with relatives. He had not had much experience of "tentative" forceps; in the cases that came to him the forceps had generally been used "all out." When it was necessary to intervene after the uterus had become dry and irritated, he first allowed the patient a considerable time to recover from shock and gave morphia; intervention should only be done with a deep anæsthetic. Instrumental rotation was very dangerous in the primigravida, whose vaginal walls had not been dilated before. His limited experience of Kellan forceps had not been encouraging.

Prof. SHAW, in reply, agreed in condemning coal-tar antiseptics. He recounted the system by which a north country practitioner charged a composition fee, performed careful antenatal examination, and employed capable midwives to attend all normal confinements for him. He himself administered after-care, but only attended confinements when conditions were abnormal. He took full responsibility, but by eliminating sources of complication at the outset saved endless trouble and compulsion by relatives. The development of this method meant training the public rather than the profession.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

UNDER the presidency of Prof. E. H. KETT (London) a discussion on the

PATHOLOGY OF ENCEPHALOMYELITIS IN VIRUS DISEASES AND EXANTHEMATA

was opened by Prof. H. M. TURNBULL (London), w dealt principally with post-vaccinal encephalitis. order to discover the exact cause of this conditi several questions, he said, required an answer. Is encephalitis caused by the essential virus of vacci tion lymph, or by some other infection introdu at vaccination, or, does the vaccinal virus excite sc latent infection? Further, if an agent other t the vaccinal virus is the cause, are the histolog results due to a combined action with vaccinal vir Comparative histology was the speaker's chief met of dealing with these questions. In the cases of p vaccinal encephalitis which he had studied hims and in the cases described by others, he had foun remarkable similarity in histological appearances. the naked eye the brains from most of these c showed congestion and œdema with hæmorrhage i the leptomeninges and subdural space. The sp cords contained one or two punctiform hæmorrha and in some cases there was blurring of the lin demarcation between grey and white matter. seven out of eight of the speaker's own cases t were found on microscopical examination f changes extending from the cerebral cortex to lumbo-sacral cord, with maximal lesions in the la situation. In the eighth case affection of the sp cord was greatest in the thoracic segments. Perc had found the most severe lesions in the pons upper medulla, while the maximal cord lesions v in the lower thoracic segments and lumbo-sa enlargement, Schürmann in the pons and medu and Lucksch in the pons and substantia ni Schürmann also found a fairly severe affection of optic tracts and nerves. The speaker had found white matter of the cerebrum more affected than grey, but in the central nervous system as a w the grey matter was more affected than the wl Other describers had made similar findings. A and subacute types were described. In the a type there is infiltration of the meninges with var round cells and endothelial cells chiefly round veins. The vessels are engorged and occasi hæmorrhages occur. In the brain and cord subst there are also small hæmorrhages with congestion, the essential change consists of perivascular marginal zones of demyelination. The perivasc zones form wide "sleeves" which surround vessels for long distances. Such vessels are al always veins. The marginal zones are found r frequently along the edges of the ventral fissur the spinal cord but also occur elsewhere at the phery of the cord. Schürmann found them als several situations in the cerebrum. Under magnification the zones appear sharply defined, within such zones, except at the margins, demye tion is usually complete. Only a fraction of the cylinders survive. The glial fibres immediately ar the vessel are sometimes thickened and give a pos reaction for fibrin. Further from the vessel fibrils form a wide-meshed net and frequently ap diminished in number. The changes in the mar zones are similar, but the speaker had not fibrinoid thickening of the perivascular glial f in these situations. Perdrau had found inci demyelination free from glial cells around n vessels, but in conspicuously affected zones the n glial fibres usually contained a great numbe proliferated glial cells. The bulk of the cells pr have been shown to be microglia and to co myelin and fat. In addition, however, neutr leucocytes occur when inflammation is int Proliferated glial cells extend beyond the demyelin zones and cause a diffuse infiltration in those re which are most severely affected. Infiltration o

ntitial sheaths is an infrequent and incon-uous feature. In addition to the perivascular marginal lesions, Perdrau found isolated and enerated fibres throughout the nervous system. bodies of the neurons are remarkably well erved. There is often clumping of the neuro-matin, but loss of angularity and complete osis are rare. In the subacute type the adventitial ths are distended with large fat-granule cells. perivascular zones of demyelination may be ty and narrow in some cases, whilst in others may coalesce to form large areas. Prof. Turnbull ntained that the changes described are clearly inct from those of poliomyelitis and encephalitis argica, and belong to the group of conditions acterised by demyelination.

his group includes certain examples of the dis-inated myelitis of Westphal, disseminated phalomyelitis of later writers, disseminated rosis, and encephalitis periaxialis diffusa. The ker added that a condition similar to post-inal encephalitis occurs independently of recent ination and observed exanthemata. He cited eral examples described by various authorities. ilar histological changes had been found in the eral nervous system as a complication of exanthe-a. Some of the cases occurring in measles, though ntially similar, present certain differences. There ld be little doubt that similar changes occur in ll-pox and probably after antirabic treatment, occurrence in mumps and chicken-pox was ertain. The cardinal point of difference between se changes and those of acute disseminated sclerosis hat the whole length of a vessel is surrounded by yelination in the former and only a segment in latter. The pathogenic processes in the two ditions, however, are essentially similar and the erent pictures may simply represent modified tions to a single agent. Regarding nomenclature, order to avoid confusion with other varieties of ephalitis, the speaker suggested, in his concluding arks, that the term "disseminated myelitis of the t-vaccinal type" should be applied to the con-ions he had described, thus grouping together ditions having a similar histological appearance.

Prof. J. McINTOSH (London) declared that the non-ulent variety of encephalomyelitis is usually the lt of virus infection. He then dealt in sequence h the manifestations of this condition in various ases. In poliomyelitis the incidence of encepha-is is low, but fatal cases often present slight cerebral ons with scattered areas of perivascular infiltra-n. When the disease is produced in monkeys, the ximal lesions are in the cord no matter how the ction is made. In encephalitis lethargica the main hological lesion is in the basal ganglia of the brain. re is perivascular infiltration, chiefly of lympho-es and plasma-cells. There is also infiltration of the ivascular parenchyma and glial proliferation. The ve-cells are not usually affected. The diseases, he lared, could be transmitted to monkeys, the lesions urring showing great similarity to the natural ction in man. Some experimenters had declared t the lesions obtained were due to spontaneous ephalitis, but Prof. McIntosh maintained that the ons he had obtained were similar to those in man, t quite different from the lesions of spontaneous ephalitis in animals. He next drew attention to ction of the nervous system in small-pox. He cribed in some detail the appearances presented the brain of a child who developed cerebral ptoms after a mild attack of small-pox. Histo-ically the lesions proved to be very similar to those post-vaccinal encephalitis, the features of which been dealt with by Prof. Turnbull. The incidence ncephalitis following vaccination was now generally nitted, continued the speaker, the condition mani-ing itself 10 to 14 days after vaccination. Dealing h the ætiology of post-vaccinal encephalitis, Prof. Intosh summarised the histological findings in this dition and maintained that they constituted a v pathological entity, in which the lesions are distinct from those in poliomyelitis and encephalitis lethargica. In order to prove that the vaccinal virus is responsible for the condition, it is essential that lesions of a closely similar nature should be produced by animal inoculation. Material from the central nervous system of cases of vaccinal encephalitis when injected intracerebrally produced only little disturbance. These negative results, it was considered, demonstrated the absence of the virus of encephalitis lethargica and poliomyelitis. Using vaccinal virus itself for inoculation, intracerebral injection into rabbits produced a fatal encephalitis, but there was great difficulty in carrying out a sequence of inoculations from one animal to another with positive results. Levaditi had prepared a highly virulent strain called neuro-vaccine which could be successfully carried from one animal to another. A similar strain had been prepared by Prof. McIntosh. The brains of animals thus treated showed definite encephalitis, extensive meningeal lesions, and sometimes indications of perivascular demyelination. Further, intravenous injections of these virulent strains of vaccinal virus produced changes in the internal organs similar to those occurring in fatal cases of post-vaccinal encephalitis. These lesions are focal areas, whitish in colour, and about the size of miliary tubercles. They differ from tubercles in showing more evidence of fibrosis. No tubercle bacilli could be demonstrated in the lesions and they were regarded as granulomata resulting from multiple foci of some virus. From these experiments it has been concluded that the vaccinal virus is the cause of post-vaccinal encephalitis. Encephalitis, continued the speaker, has been recorded in cases of chicken-pox, measles, and mumps, but such a complication is extremely rare. In the case of chicken-pox, clinical records show that symptoms suggesting involvement of the nervous system occur from time to time, and in the literature some dozen cases of encephalomyelitis have been described. Recovery in most cases was complete in a few weeks. Fatal cases of chicken-pox are so rare that no histological details are available. Nervous involvement in measles and mumps is still more rare. Two cases of encephalitis complicating measles have been described by Wohlwell, who regarded them as showing a close resemblance to the lesions of post-vaccinal encephalitis. Encephalitis in typhus fever is a constant feature and may be regarded as part of the disease process. Microscopic examination reveals the constant presence of lesions of the central nervous system and internal organs. In general the encephalitic lesions resemble those of variolar and post-vaccinal encephalitis. The pathological changes consist essentially of proliferations of large clear cells into the surrounding nervous tissue, with infiltration of inflammatory cells. In some lesions the cells are compact, while in others the perivascular outgrowth is diffuse. The proliferated cells are generally considered to be glial in origin, but Wollbach and his co-workers are of the opinion that they are mesoblastic and derived mainly from the blood-vessels. As a rule, gross lesions are not visible to the naked eye, and the meninges show only a slight inflammatory reaction. Typhus has been experimentally transmitted to monkeys by intraperitoneal injections of blood from infected cases, and to guinea-pigs by injection of pathological tissue and lice from human cases. The virus can be carried from guinea-pig to guinea-pig indefinitely. Lesions identical with those in man were found in the central nervous system of these animals. Prof. McIntosh, in summarising, said, non-suppurative myelitis can occur in a number of virus infections, in particular poliomyelitis, encephalitis lethargica, small-pox, vaccinia, chicken-pox, measles, mumps, and typhus fever. He stated that the encephalitis may occur as part of the disease process or as a complication, and investigations of these conditions show that a histological picture of a certain type can be assigned to each. Doubtless, he said, further studies will bring forward additional new types, as the differential features are better understood. The characteristic histological appear-

ances of encephalitis lethargica and post-vaccinal encephalitis, together with the fact that lesions comparable with those found in natural disease can be reproduced experimentally in animals by the inoculation of virus containing material, is strong evidence that the encephalitis is actually produced by the infecting virus in each of these two conditions.

Dr. J. G. GREENFIELD'S paper was read in his absence by Prof. HADFIELD. He dealt with encephalomyelitis in measles and pointed out that this complication appeared to be increasing in recent years. He described in some detail the post-mortem findings in a girl of 9 years in whom there developed convulsions, high temperature, and coma four days after the measles rash had appeared. The similarity of the findings to those in post-vaccinal encephalitis were demonstrated.

Dr. S. P. BEDSON considered some aspects of the experimental side of the problem. He pointed out that the virus of herpes febrilis should be carefully considered in dealing with nervous manifestations in virus diseases. This virus has been considered by some authorities to be the causal factor in encephalitis lethargica, such view being based on the isolation of the virus of herpes febrilis from such cases. In encephalitis lethargica, however, no skin lesions occur. Dr. Bedson claimed that an antibody is developed in herpes infection, but he could find no such antibody in encephalitis lethargica. The herpes virus is highly neurotoxic in rabbits, and further, spontaneous encephalitis also occurs in these animals. Great care is therefore necessary in interpreting results.

Prof. G. HADFIELD (London) described the appearances in a case of post-vaccinal encephalitis. He had also studied in detail the nervous system of four children who had died from accidental causes shortly after vaccination. In these cases no changes were found. The histological picture in the encephalitis case corresponds with that of other workers. The importance of investigating the condition and reaction of the neuroglia was emphasised. The histological picture in post-vaccinal encephalitis seems to be standard but not specific because of similarity in measles and small-pox. In early lesions of disseminated sclerosis there is histological similarity to the above lesions, but the clinical features suggest a different ætiology.

Prof. J. H. DIBLE (Cardiff) expressed considerable doubt on the interpretations of experimental work in encephalitis lethargica. He said that in the rabbit the positive results obtained were inextricably mixed up with the herpetic virus. If herpes and encephalitis virus are the same thing then it exhibits different properties in human and rabbit brains. It is impossible to produce keratitis with fresh material from encephalitis cases, but when encephalitis has been produced in rabbits the virus recovered from the brain will produce keratitis. Clinically, encephalitis rarely or never presents herpes. Herpes is common in pneumonia, but cerebral affection is absent or rare in this condition. Prof. Dible, Flexner, and others had failed to infect rabbits with encephalitis lethargica. Flexner had also failed to infect monkeys. Those who have produced apparently positive results show marked disparity in the time of incidence, and it is difficult to believe that one and the same virus could exhibit such eccentricities. The speaker expressed doubt that the condition of encephalitis lethargica has ever been transmitted to animals.

Prof. J. CRUICKSHANK (Aberdeen) drew attention to the incidence of herpes infection in bacterial diseases, and sought information on the incidence of encephalitis in such cases. He further described an interesting happening in which a stock of calf lymph which was used without ill-effects in Spain, when used in Holland produced a number of cases of post-vaccinal encephalitis. Was this the result of a dormant virus being stimulated?

Prof. MCINTOSH, in reply, said he was quite satisfied that the lesions he had obtained were not those of herpes febrilis or spontaneous encephalitis.

The PRESIDENT summed up the discussion wh he said, had brought out clearly the fact that a f of encephalitis was definitely associated with vacc tion. Whether the vaccine was the actual caus the encephalitis or whether it served merely to l up an already existing latent infection was important from the practical standpoint. If one assaulted another with a fatal result, the fact that victim might not have died had he not suffered f heart disease would not save the assailant f punishment. Similarly, vaccination could not held blameless even if it only lighted up a la infection. The existence of cases of encepha following vaccination was now established, official figures as to the proportion these cases bor the total number of vaccinations performed were available. Since allusions to the complication frequently appeared in the lay press, he had hc that the discussion would have brought out s information on this point, so that the medical pr sion would be in a position to reassure the publi

An interesting exhibition of pathological specin was on view at University College throughout Association's meeting.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEAL

THE following table gives some 1927 stati of five Lancashire districts :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-r per 10 births	
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Diarrhœa, &c., under 2 years.
Blackburn C.B. (124,500)	13·7	14·9	0·88	1·28	4·0	2·2	77/37	7·0
Bolton C.B. .. (178,300)	15·1	13·8	1·04	1·32	3·2	1·9	75/36	7·4
Bury C.B. .. (56,770)	13·7	14·3	1·02	1·35	3·8	2·3	79/35	5·1
Eccles B. .. .. (45,390)	15·6	12·7	1·06	1·65	2·3	2·2	61/24	4·2
Swinton and Pendlebury U.D. .. .. (34,750)	12·2	10·0	0·86	1·14	2·0	1·4	75/40	2·3

C.B. = County Borough. B. = Borough.
U.D. = Urban District.

Blackburn.

Dr. Oscar M. Holden reports a sunless year an abnormal rainfall—958 hours of bright suns recorded at the corporation hospital as comp with 1114 in 1926, and 43·3 in. of rain as comp with 40·9 in. Dr. Holden thinks the extent o clay drifts has some bearing on the prevalenc the rheumatic affections, which are a promi feature in the sickness records. The year was o depressed industrial conditions with much u ployment in the town's chief industry of co weaving and its subsidiary branches. The popul of Blackburn reached its zenith in 1914, and in for the first time since the war, the deaths exce the births—namely, by 162.

The respiratory group of diseases bulks largely in the death returns of the town, and predominant causes suggested are unfavou climatic conditions coupled with a dirty atmosp Deaths due to respiratory diseases are marl

greater among cotton operatives than among the general population at all age-periods. The tuberculosis death-rate shows very little change. Only a very small proportion of the contacts avail themselves of the facilities afforded by the tuberculosis dispensary. It is not practicable with the present staff to arrange for home examination of contacts, but the coöperation of private practitioners would be very valuable in this branch of work. There is great need for adequate after-care for cases of pulmonary tuberculosis.

The antenatal clinic was attended by 480 prospective mothers, the total births being 1702. Dr. Holden is disappointed with the number of patients sent to the clinic by the midwives, who attended 81 per cent. of the confinements during 1927. He further points out that no improvement has been brought about by the recent requirement of the C.M.B. that practising midwives should carry on antenatal work or (if they feel unable to do so) send their patients to the antenatal clinic. In 1925 7 per cent. of the cases attending the clinic were sent by midwives, in 1926 12·3 per cent., and in 1927 11 per cent. The maternal mortality is high, the figures for the last six years being 6·8, 6·7, 5·0, 5·7, 8, and 7·6. The stillbirth-rate for 1927 was 5 per cent. The Springfield Maternity Home has accommodation for 20 cases and is recognised as a training hospital for pupil midwives. The medical officer of health has power to remit the minimum fee of 1½ guineas per week in cases of proved necessity, and there is no reason why any mother, whose home surroundings are unsatisfactory, should not avail herself of the facilities and comforts of the home. Nevertheless the home is not used as much as it might be. There were only 220 cases admitted during 1927, of whom six were for antenatal supervision. From 400 to 500 cases could be readily accommodated.

The death-rate from respiratory diseases among the pre-school children was especially high owing to outbreaks of measles and influenza during the first quarter. Although there has been a distinct fall in the infant mortality-rate since 1920, the death-rate in the 1–5 years group shows no such tendency. Blackburn is more fortunate than most industrial towns in its housing conditions. There is no real slum property and no universal overcrowding, the average rooms per person being 1·1. And yet there is a long list of applications for corporation houses, occasional overcrowding caused by subletting, and a growing tendency for tent sheds and caravans to be used as substitutes for houses.

Bolton.

Dr. C. W. Paget Moffatt reports that for the first time since 1922 the Registrar-General has estimated an increase in the population of Bolton, which makes it nearly as high as it was in 1909—viz., 178,667. The scheme for the substitution of water-closets for privy middens has slowed down owing to difficulties as to sewers and prospective demolition of property. Bolton is coöperating with the Manchester regional smoke-abatement committee. The intention is to have the same by-laws in all the areas of the region, but up to now the regional committee has not been able to formulate by-laws acceptable to the Ministry. There are 226 factory chimneys in Bolton, and Dr. Moffatt thinks there will be no real abatement of the smoke nuisance in industrial areas until soft coal is replaced by smokeless fuel, and that a great deal will be accomplished in this direction before long. By-laws are needed for houses let in lodgings. Strenuous efforts are being made to reduce the nuisance from vans. At the close of 1927 there were 42 living vans as compared with 73 at the close of 1926. Most of the slaughtering in Bolton is done in private slaughter-houses owing to the fact that the public abattoirs are too small and out of date. The new houses erected were 510 municipal, 490 subsidised houses by other persons, and 81 unsubsidised, a total of 1081. Overcrowding is not prevalent and the number of inhabitants per house has decreased steadily from 4·64 at the census of 1901 to 3·86 in 1927. Forty-seven houses were demolished during the year.

The meat regulations have brought about a marked improvement in the handling of meat, but attention is drawn to the very insanitary practice of leaving the feet on the dressed carcasses of lamb and mutton. The frequently filthy condition of the feet is liable to cause dangerous contamination of the meat.

About three-fifths of Bolton's milk comes from 2700 cows stalled in the borough; one-fifth from outside farms is pasteurised by the Coöperative Society; and the remaining fifth comes from other outside farms. The "inside" cows are regularly inspected by the veterinary surgeon, who is usually accompanied by a sanitary inspector to look after the hygienic condition of the dairy farm. As the result of routine veterinary inspection, 6 cows giving tuberculous milk were found and slaughtered. The cows slaughtered under the Tuberculosis Order numbered 32, of which 9 had tuberculosis of the udder, 1 was giving tuberculous milk and had other tuberculous lesions, 6 showed tuberculous emaciation, and 16 had chronic cough and definite signs. One farmer was fined £5 for failing to notify a cow suffering from tuberculosis of the udder.

Dr. Moffatt shows that Bolton is doing everything recommended by the Ministry for the prevention of maternal deaths, but expresses his opinion that a real improvement in the training and status of midwives is needed. A longer and more thorough training would help to exclude from the profession those who adopt it, not as their real life's work, but as a means of adding to the family income.

Bury.

Dr. G. Granville Buckley says that the scheme for the conversion of privies into water-closets has made rapid progress, but that there are about 450 which cannot be dealt with as there is no sewer available. The sewage disposal works have three systems following the sedimentation tanks—namely, single-contact beds, percolating beds, and the activated sludge process. During 1927 six samples of the joint effluent were satisfactory and two slightly unsatisfactory, as judged by the inspectors of the Mersey and Irwell Joint Committee. The public abattoir is modern in every respect. Of the carcasses, bulls were affected with tuberculosis to the extent of 2·5 per cent.; oxen, 0·21 per cent.; cows, 10·25 per cent.; heifers, 0·55 per cent.; and pigs, 4·22 per cent. The infant deaths numbered 62, and there were 34 deaths of children between the ages of 1–5. Of the three deaths making up the maternal mortality one was due to puerperal fever, another to "septic abortion followed by peritonitis and septicæmia set up by douching in an attempt to procure abortion," and the third to "septic abortion following on accidental abortion. Peritonitis (general)." There was a fourth maternal death of a woman, who had attended the antenatal clinic and who developed kidney trouble the tenth day after labour.

Eccles.

Dr. J. E. Spence points out that there were no deaths of children aged 1 to 2 years from gastro-enteritis in 1927, but that 13·3 per cent. of the deaths at this age-period since 1914 have been due to this cause. The fall in mortality at the age-period 2 to 5 has not been regular, but shows fluctuations caused by the respiratory diseases. Since 1914 28·1 per cent. of the deaths in this age-group have been due to bronchitis and pneumonia, 15·9 per cent. to measles, and 8·4 per cent. to whooping-cough. The child welfare work and school medical work is closely coördinated. Each health nurse attends the centre on one afternoon a week and, as far as possible, the mothers in her area come on that afternoon. Each child during its first year is seen by the nurse on

an average 29 times, during the second year 8·9 times, and during the third year 4·8 times. The supervision continues during the 3–5 age-period, when about half the children attend school. Early treatment of the pre-school child for squint, dental trouble, and other ailments is thus made possible. "Ultra-violet" treatment is provided at Barton-upon-Irwell Hospital for rickets and debilitating conditions, but Dr. Spence is not greatly impressed with its value, if separated from other hygienic measures. There is a difficulty in getting the "lazy, indolent mother" to persevere with any treatment for rickets, as she trusts to the deformities disappearing without treatment and does not appreciate that the deformity is only one effect of the disease. The water from the two swimming baths is filtered through Bell's filters. The men's bath was closed for repairs after the water had been in use from January, 1923, until Oct. 31st, 1927. During the whole of this period the chemical and bacteriological examination of this water was satisfactory. The women's bath is chlorinated as well as filtered, but the analysis taken on Sept. 20th shows more chlorine in the water of the men's bath than in that of the women's. Notwithstanding the extensive provision of municipal houses, there are too many houses occupied by more than one family, and many cases of hardship therefrom. The rent charged to the lodging family in many instances exceeds the rent of the whole house. During the year 19 municipal houses, 34 subsidiary houses, and 3 houses of a larger type were erected, while 24 houses were demolished. Ninety municipal houses are nearing completion, and the corporation are considering a scheme for 68 more. There are 800 families which still require to be housed and there are no signs of the shortage of houses being overtaken.

Swinton and Pendlebury.

Dr. H. C. Mulholland, who is also school medical officer and certifying factory surgeon to the urban district, says the staff engaged upon orthopædic, dental, and aural work for the schools does similar work for the maternity and child-welfare centres. The district, except in a few outlying cases, is on the water-carriage system. The sanitary inspectors have been sent for a course of special training in dairying. A table shows that out of 52 routine samples of mixed milk, tested by biological methods, nine contained tubercle bacilli. Systematic veterinary inspection of the farms has been in force since 1924, and the veterinary surgeon is accompanied by the sanitary inspector, who sees to the sanitary condition of the dairy farms. The council has adopted the limit of 2 minutes in the half hour for black smoke, and legal proceedings were successfully taken and fines inflicted during the year in three instances. Since 1920, 32 cases of encephalitis lethargica have been notified, including one doubtful case in 1927. The present condition is that 8 have died, 17 are severely ill, 4 are slightly ill and fit for light work, and 3 are apparently normal. There was no evidence that case-to-case infection, insanitation, or overcrowding were causal factors. The health visitors have undergone a short course of training at the Manchester Royal Eye Hospital on the nursing of ophthalmia neonatorum. The four cases notified in 1927 all made a complete recovery. One urinary typhoid carrier resident in the district is kept under observation, but did not give rise to any cases in 1927. There were 709 births, and 81 expectant mothers attended the antenatal clinic, which is conducted by a consultant. Caravans tend to increase in the district, and the occupants are usually dependent upon neighbours for water and sanitary conveniences. There are just over 5000 working-class houses in the district, and 309 of these houses are overcrowded. Houses needed are estimated at 510, 210 for the unsatisfied demand, and 300 to provide for the demolition of insanitary property. No council houses were completed during the year, but 182 are in course of erection.

INFECTIOUS DISEASE IN ENGLAND AN WALES DURING THE WEEK ENDED JULY 21ST, 1928.

Notifications.—The following cases of infectic disease were notified during the week:—Small-p 173 (last week 177); scarlet fever, 1528; diphther 900; enteric fever, 54; pneumonia, 706; puerpe fever, 43; puerperal pyrexia, 94; cerebro-spinal fev 7; acute poliomyelitis, 5; acute polio-encephali 4; encephalitis lethargica, 21; dysentery, 3; op thalmia neonatorum, 130. No case of cholera, plag or typhus fever was notified during the week.

The cases of small-pox were notified from the follow 19 counties:—London, 9; Buckingham; 1; Derby, 1 Durham, 53; Essex, 3; Huntingdon, 1; Kent, 1; L caster, 5; Northampton, 1; Northumberland, 12; N tingham, 2; Soke of Peterborough, 2; Stafford, 11; Surr 1; Yorks East Riding, 3; North Riding, 12; West Ridi 24; Glamorgan, 13; Monmouth, 7.

The number of patients in the Infectious Hospitals of Metropolitan Asylums Board on July 24th–25th was follows:—Small-pox, 23 under treatment; scarlet fe 1771; diphtheria, 1849; enteric fever, 19; measles, 3 whooping-cough, 196; puerperal fever, 18 (plus 12 babie encephalitis lethargica, 67; poliomyelitis, 2; "ot diseases," 22. At St. Margaret's Hospital there w 21 babies (plus 11 mothers) with ophthalmia neonatorum

Deaths.—In the aggregate of great towns, includ London, there was no death from small-pox, 5 from enteric fever, 28 (5) from measles, 5 (3) fr scarlet fever, 20 (1) from whooping-cough, 26 from diphtheria, 36 (9) from diarrhœa and enter under two years, and 21 (2) from influenza. The figures in parentheses are those for London itself.

The four fatal cases of enteric fever outside London were reported from Southampton, Sunderland, and Newcastle-Tyne (2). Of the 23 fatal cases of measles outside Lond 6 were reported from Liverpool. Of the 19 cases of who ing-cough outside London, 3 were reported from Birmi ham. In the same week Glasgow reported 6 and Belfas Belfast also had 6 fatal cases of measles. The deaths fr diarrhœa are still diminishing.

The number of stillbirths registered during the w was 270 in the great towns (corresponding to a r of 38 per 1000 births), including 53 in London.

Deaths from Small-pox.—A supplementary monthly statement shows that the returns for the month June included, in addition to the deaths alre shown in the Weekly Return, 6 deaths certified as due to small-pox either as principal or contributory cause. These deaths were assigned to the follow areas:—Ilfracombe U.D., 1; King's Lynn M.B., Thame U.D., 1; Keighley R.D., 1; and Gelli U.D. (Glam.), 1.

HERTFORD BRITISH HOSPITAL, PARIS.—The K and Queen have given their patronage to this hosp which was founded during the seige of Paris in 1871 by late Sir Richard Wallace. In 1879 Sir Richard erect new building which his widow handed over to the Br Government. The British Ambassador in Paris for time being is the honorary president. The hospit situated at Levallois-Perret, outside the fortifications, has 46 beds.

EXTENSION OF LEEDS GENERAL INFIRMARY.—Particulars are now available of the proposed large exten of this institution which, together with the discharge o bank overdraft, will cost £250,000. There is to be a p patients' block of three floors in which patients will some 5 to 7 guineas a week, according to the degr privacy enjoyed. It is hoped that this block will he remove the difficulties caused by the rapid growth of accident cases which are costing the infirmary £4000 a while the donations traceable to those concerned amou less than £100. Another block, which is to be built will provide for another 100 non-paying patients waiting-list has rarely less than 1000 names. The bui of these two new blocks will increase the total ac modation of the infirmary itself and the branch Cookridge from 632 to 800 beds. The present av annual deficit is £25,000 and the extensions will increas cost of maintenance from £104,000 to £120,000 a year

MEDICINE AND THE LAW.

eath Certification: Date of Certifying Practitioner's Last Visit.

THE primary purpose of the coroner's inquest is o of public safety—the detection of foul play, and c sequently the prevention of crime. The result of t amending legislation of 1926 was to interlock the l relating to coroners and the law relating to the c tification of death. It now is, or should be, as d icult as human foresight can make it to conceal a d th or to dispose of a body without adequate o cial knowledge of the circumstances of the death. I also is, or should be, as difficult as human fore- s ht can make it to dispose of a body by burial or c mation when death has not in fact taken place. T ese safeguards for the public have naturally not b n evolved without enacting an elaborate code of s tutes and regulations. There is some reason to t nk that medical practitioners, on whose coöpera- t n the whole system depends, are not yet fully a are of the new legal position. The Registration t of 1926 provided for a "prescribed" form of c tor's death certificate, and the form thus pre- s ibed requires the doctor to state when he last s w the patient alive. Part IX. of the new r gulations—the Registration (Births, Stillbirths, D aths and Marriages) Consolidated Regulations 1927—is headed, "References to Coroner a d Registration after Reference—Stillbirths and D aths." One of the occasions on which the registrar u st report to the coroner before registering a death i where "it appears to the registrar from the parti- l lars contained in the medical certificate or other- w se that the deceased was seen by the certifying m dical practitioner neither after death nor within 1 days of death." Those who are apprehensive of t e risk of a person being buried alive will reckon t is regulation as intended to avert that danger as w ll as to lessen the chance that death might be c used by violence or poisoning in the interval b tween the practitioner's last visit and the date of d ath.

At a recent inquest, held in Southwark by Dr. . J. Waldo upon the death of a woman aged 81, t e coroner explained that the case had been reported t him by the registrar under the regulation already c ted. It appeared that the medical practitioner h d certified death to be due to natural causes, and t at his last attendance had been seven weeks before t e date of death. In these circumstances the coroner o dered a full post-mortem examination by an inde- p ndent pathologist, and requested the attendance o the certifying doctor at the inquest. The patho- l gist's evidence agreed with the certificate, and thus t e inquest merely confirmed what was already upon r cord. In answer to the coroner the pathologist a reed that, without careful expert examination of t body, it was not safe to assume that death had a tually taken place. He cited an instance where t e police had recently called him in to examine a y uth in a state of catalepsy. The patient appeared d ad but, on examination, a feeble pulse beat was f und in spite of commencing rigor of the muscles o the jaw, absence of eye reflex, and dilated pupils—t ree characteristic signs of death; appropriate t eatment ended in recovery. Dr. Waldo, in sum- m ing up, described the state of the law in connexion w th death certification, registration, and disposal of t e dead as unsatisfactory and dangerous. It was, he s id, of vital importance to the public that the view a d external examination of the body by the certi- f ing doctor should be made compulsory before b rial. Such a course would be a safeguard against a y possible false assumption of death. Dr. Waldo's p int is that a statutory period of 14 days, without a y further view of the body, is neither a safeguard against premature burial nor a trustworthy precaution against the non-detection of foul play. He would have the present law amended in the following three respects: first, compulsory view of the body by the certifying practitioner who attended the deceased (with payment of a small fee for such duty) prior to registration of death by the local registrar; secondly, registration without report to the coroner, provided the certifying doctor had last attended his patient within 14 days of death and had also viewed the dead body; thirdly, statutory notification by the registrar to the coroner of all deaths of patients not seen by the certifying doctor within the 14 days period, to be followed by public inquest.

It is probably a surprise to some practitioners to find that coroners can, and do, order post-mortem examination and inquest where the certifying doctor has not seen the deceased within 14 days of death. Each case must be judged upon its own set of facts, and it may well be that one coroner would not take the same view of his responsibilities as another. Whether the law will soon be changed is doubtful. Parliament has only lately hammered out the new changes, and the arguments for different changes were fully discussed when the present ones were adopted. Sir Kingsley Wood, replying to a question by Mr. T. E. Naylor, M.P. for Southwark, in the House of Commons on July 11th, held out no prospect of further legislation at present.

A Point in the Coroner's Law.

A coroner asks a practitioner for certain information as to the cause of death of a deceased person to enable him to decide whether or not he will hold an inquest. The information desired in this case was technical both as to fact and opinion, and was given out of professional knowledge and experience. On consideration of the information the coroner decided to hold no inquest, and having held no inquest he paid no fee. Quite amicably, the doctor and the coroner have sought our opinion, or reference to any opinion that has been previously expressed in similar circumstances. The doctor considers that a fee is due to him, and the coroner, allowing the justice of the claim, replies that he has no power under the law to satisfy it.

It seems to us clear that the doctor should be paid, and equally clear that the coroner should not be at the expense of a fee for which he would be surcharged. A sentence in the Statute would suffice to meet the case, but changes in an Act of Parliament are not readily brought about; and while the situation may occur with sufficient frequency to suggest a demand for legislation, it is not clear to us that the existing position is not preferable. The doctor who supplies the coroner with the needful information is relieved of a responsibility to give medical evidence, and many practitioners would welcome this, while the relatives are spared a procedure that they always dislike unless they have reason for promoting an inquiry. In all such cases the coroner would know the feeling of the family and would hold the inquest. One natural source for the fee would be estate of the deceased, if there were any estate, but executors could not be bound to admit the doctor's claim.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Settlement of a Conflict Between the Profession and a Sick Club.

WITHIN the last few weeks a serious conflict arose between the entire medical profession in Vienna and the vast organisation called the Sickness Insurance Club for Civil Servants. This latter has about 280,000 members, and had hitherto offered free choice of practitioners to its members. Recently the administrative body of this club has tried to remove the bulk of the profession from the free choice list; doubtless the intention was gradually to substitute

for the free choice system—advantageous both to the profession and the patients, but not to the administrative body—a system of appointed doctors responsible only to the board of the club. As the remonstrances of the medical representatives were useless, from June 11th all medical work for the club was refused, and the members were received only as private patients. They were, however, entitled to demand compensation and a refund of the fees paid to the sick club. This led to troublesome conditions for all parties concerned, but mostly for the managing board, so that after some three weeks it was found more convenient to arrive at an understanding. The arrangement provides that in future the board of the club will not seek to introduce innovations of any kind pertaining to therapy without the consent of the medical representatives; the extent of specialist service to be available will be controlled by a board chosen equally by the club and the profession. Some minor problems were settled at the same time, in a sense favourable to the practitioners, so that this strike—the first instance of a medical fight on the lines of trades-unionism in this country—can be looked upon as having ended in favour of the doctors.

Decapsulation of the Testicle as a Means of Rejuvenation.

Intense public interest seems to be aroused by any suggested methods of regaining lost youthfulness. Prof. Ullmann (Vienna) has now published his observations on the method of "decapsulation," practised by him since 1915, but hitherto unpublished. He has had the opportunity of making transplantations of testicles in cases of ectopia testis, and of examining such cases after a few years. In each case new blood-vessels had formed, but only if the transplantation took place in individuals belonging to the same blood group or a related one. Otherwise the transplanted organ was gradually absorbed. This he holds to be the fate of the testicles transplanted from monkeys or other animals (Voronoff). In such cases transplantation acts only as a stimulus, like a non-specific protein injection. Ullmann claims now that the safest and most reliable method of producing lasting hyperæmia—and thus a hyperproduction of the hormones—in the testis is to decapsulate it and thus offer it means to expand, since the primary reason for diminished function of the testes is, according to him, the increasing intra-testicular pressure with lessened blood-supply, due to sclerotic processes. Prof. Ullmann lays stress on the fact that, in 1915, when the problem of blood-group relation was unknown, transplantation was applied in a wrong way, and that now his method, which is very simple, should be tried in suitable cases.

Resignation of Prof. Wagner-Jauregg.

The well-known neuro-pathologist and latest recipient of the Nobel prize for medicine, Prof. Wagner-Jauregg, has resigned his post as chief of the clinic for neurology and psychiatry in Vienna, having attained the age of 71. His farewell lecture, held a few days ago, was marked by a number of farewell speeches from his pupils. The professor himself completed his task by delivering a splendid lecture on the treatment of tabes, after which Prof. Redlut and Dr. Poetzl, on behalf of the former and the present pupils, spoke of the importance of his contributions to the advance of neurology, notably in the prophylaxis of thyroid enlargement and the malarial treatment of general paralysis of the insane and tabes dorsalis. The office of Wagner-Jauregg will be filled shortly either by Prof. Economo (Vienna), well known for his researches on encephalitis lethargica, or by Prof. Poetzl (Prague), the first-named being regarded as the more likely candidate.

Statistics Concerning Suicides in the Half Year 1928.

The public records for the first half of 1928 show that 1528 persons attempted to commit suicide in Vienna, of whom 507 attained their object. These figures show a marked and constant increase in comparison with the years before the war and the period immediately following it, the number of attempts being double those recorded in 1917. It is remarkable that while the same number of men and women tried to kill themselves, only 199 women succeeded in doing so, against 308 men. As regards the causes of suicide, 287 (106 of these were men) tried to destroy their lives for family troubles; 73 (165 men) because of poverty, 160 (80 men) on account of incurable illness, 160 (55 men) an account of love affairs, 130 persons (78 men) were insane; 41 men and 5 women despaired of their financial position or outlook, 17 men and 22 women were prompted by severe family loss. In 433 cases (221 men) the reasons were unknown.

American Post-graduate Students in Vienna.

This summer, as usual, a large number of American doctors have made our university their temporary home. In the last week of June a group of over 60 doctors, under the leadership of Prof. George MacKenzie, of Chicago, have been here, having arranged beforehand to attend a number of special courses in the clinics of Profs. Neumann, Hejek, and Masschik (oto-rhino-laryngology) and Profs. Meller and Lindner (ophthalmology). These classes will last six weeks each, and will occupy ten hours daily, so that each student will obtain 300 hours of instruction. These zealous post-graduate students, in order to fit themselves to make the most of the instruction provided, attended classes conducted by Prof. MacKenzie, as an introduction to oto-rhino-laryngology and ophthalmology. Post-graduate courses in Vienna are much favoured by the Americans; already more than 300 have put down their names for courses in the session 1928–29. A special American Medical Association of Vienna controls and organises these courses, which are held in English.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Venereal Diseases.

IN Dr. William Robertson's report on the health of Edinburgh in 1927 reference is made to venereal diseases and to the House of Common's refusal of a second reading to the Corporation Bill. The report notes that certain forms of disease are on the increase despite all that has been said and done to educate the public. It is unfortunate that moral and social questions have been introduced to hamper us in our efforts to control the spread of these dangerous infections. Venereal diseases are much more serious than other maladies because, if incompletely treated, they may have disastrous after-effects. It would because we are aware of the serious consequences to the individual and to future generations that we desired to secure a better control of the disease in its different forms and phases. We may as well cease for the moon to come down to earth as expect to get the better of venereal diseases by voluntary methods. The great majority of infected persons will continue to present themselves for treatment, but unless we have the power to compel those who are indifferent, careless, or obstinate to rid themselves of the disease we must expect to find a continuation of mental deficiency, affections of the nervous system, miscarriages, as well as chronic and often indefinable ill-health among men, women, and children. Our effort has been arrested by dialectics. Those who have experienced the difficulties and understand the problem from actual contact with it have been seriously discouraged though not disheartened.

The Slaughter of Sheep.

A report on the investigation carried out in Edinburgh on June 14th has now been issued by Prof. Henry Dryerre, Professor of Physiology at the Roy

k Veterinary College, and Dr. J. D. S. Cameron, ysician to the Royal Dispensary. They state t 60 sheep were provided, and at their request the ggested methods of slaughter were amended and lered as follows: (1) sticking and checking, 20 ep; (2) shooting and sticking, 20 sheep; (3) oting and sticking, and breaking of the neck, 10 ep; (4) sticking and checking, 10 sheep. In the ermination of when consciousness was lost, they ed their conclusions upon the disappearance of tain cerebral reflexes. They give it as their nion that shooting and sticking is much to be ferred to sticking and checking, from the humani- ian point of view and, further, that after shooting, humanitarian benefit is derived from checking or k-breaking. They realise that sticking is necessary m the utilitarian point of view, and no objection be taken to this procedure, on the grounds that oduces pain, if shooting precedes it.

The Scottish Health League.

A meeting of the provincial council of the Scottish alth League was held recently in Glasgow, with of. Carstairs Douglas in the chair. A large and resentative General Council was elected, including ny well-known members of the medical and dental fessions, together with 94 medical officers of lth throughout Scotland. Colonel P. S. Lelean, fessor of Public Health in the University of nburgh, was elected chairman, and Dr. A. K. lmers, vice-chairman of the General Council, with David McKail hon. secretary. The following ecutive Council was elected: Dr. M. Adams McVey, .S., Dr. Thomas Adam, Dr. G. G. Buchanan, Agnes Cameron, Mr. J. Menzies Campbell, L.D.S., A. K. Chalmers, Prof. Carstairs Douglas, Dr. C. Scott Dow, L.D.S., Dr. James Kerr, Prof. S. Lelean, Dr. G. W. McIntosh, Dr. David McKail, G. V. T. McMichael, Dr. J. Hume Patterson, D. L. Radford, L.D.S., Dr. G. Y. Richardson, T. Lauder Thomson, Dr. Margaret Tod, and Dr. lmers Watson.

he Council intends to form an advisory council, health societies and social organisations operating Scotland have been invited to nominate repre- tatives. It has been decided to inaugurate nches of the League throughout Scotland, and it oped that all interested in the dissemination of wledge upon healthy living will coöperate with Council.

Larbert Colony Scheme for Adult Mental Defectives.

he directors of the Royal Scottish National itution, Larbert, are appealing for support ards the colony now being established at Larbert ate for the whole-life care of adult mental defec- s. For the last 65 years the Royal Scottish ional Institution has provided a home, care, and ning for mentally defective children, of whom e are at present over 500 in the home; but these dren have to be discharged on arriving at the of 16 or 20. The directors emphasise the dangers h this involves both for the mentally defective nselves and the community. The colony scheme been adopted by every other progressive country, has not hitherto been attempted in Scotland.

Students' Attitude to Charity.

dinburgh students have recently been considering oposal that they should run a "Charities Week" heir own instead of merely helping the organisers he Royal Infirmary pageant on Infirmary Day. suggestion, which was discussed by the students' esentative council, has not met with general oval. Such efforts are made annually in Glasgow Aberdeen, and they have hitherto met with t success. In deciding not to follow the example he students of these two cities, the Edinburgh ents were of opinion that the idea of collecting harity was being carried too far. In Glasgow, instance, the students started quite modestly. they always set themselves out to beat their previous total, with the result that the campaign is now gigantic, and they find themselves committed to a big piece of organisation. Necessarily they have only a limited amount of spare time. It is no longer an enjoyable rag, but a serious, arduous campaign, with months of preparation. Again, in Glasgow and Aberdeen the infirmaries do not organise pageants of their own as is done in Edinburgh, and the concerted effort of the students is the only one of the year in these cities.

The students will, of course, continue to do their best on Infirmary Day.

The Trend of Medicine.

The place which the physician has held in the world in the past and the place which he is likely to hold in the future were touched upon by Prof. William Wright Smith, in the course of an address at the summer graduation in medicine at Edinburgh University on July 18th. The trend of medicine, he said, was to the prophylactic. In the plant world it had been realised long ago that cure was at best difficult—prevention was the aim. How would these changes affect them in the public eye? We were still far, perhaps, from the institution of a scientific medical police. But would the tendency be for the medical man to become more and more of an official? Officials were not loved. But as long as the ethical obligations, so characteristic of the past, continued on the same high level, the favourable status of the profession was assured.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. D. G. Addison-Scott is placed on the Retd. List with rank of Surg. Capt.

Surg. Comdr. T. C. Patterson to *President*, for Medical Dept., temp.

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Lts. R. Pedlow and W. T. Donovan to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: C. B. C. Anderson, P. E. D. Pank, and G. Moulston.

ARMY DENTAL CORPS.

Temp. Capt. W. L. Pearson, Dental Surg., Gen. List, to be Capt.

Lt. (on prob.) R. W. Mather is confirmed in his rank.

TERRITORIAL ARMY.

Capt. E. Scott to be Maj.

J. R. Wright and G. C. Vaughan to be Lts.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Army Dental Corps.—Lt. H. G. L. Fletcher, from T. A. Res. of Off. (5th Bn. Foresters), to be Lt.

ROYAL AIR FORCE.

The temp. commn. of Flying Officer S. McC. Craig (temp. Lt., Gen. List, Army Dental Surgeon) is terminated on relinquishment of his Army commission.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. W. D. Miller is transferred from Class D2 to Class D1.

INDIAN MEDICAL SERVICE.

Capt. D. R. Thomas to be Maj.

Nand Lal Sah and Bhawani Das Sindhwani to be temp. Lts.

The undermentioned retire: Maj.-Gen. A. A. Gibbs and Lt.-Cols. H. Watts and W. Lapsley.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon Majs. R. I. Dacre, A. Young (ret.), and W. T. Briscoe.

BIRMINGHAM CHILDREN'S HOSPITAL.—The board of governors report that during the first six months of the present year the number of patients admitted was 2798, nearly 250 more than in the same period last year. The waiting-list exceeds 700, and two new wards are to be built to provide 40 more beds, together with an isolation block.

Correspondence.

"Audi alteram partem."

CANCER: VIRUS OR ENZYME?

To the Editor of THE LANCET.

SIR,—After what we have suffered at the hands of too imaginative reporters, it is refreshing to read your admirable leading article under the above title. At no time have we suggested that cancer in general is due to an enzyme. All that Dr. Murphy and I have claimed is that a certain tumour of fowls, commonly known as Rous Sarcoma No. 1, is produced by a chemical substance of enzymic nature and not by a virus in the ordinary acceptation of the word. I am a little surprised at your verdict that "the essential problem presented by the filterable tumour of the fowl is not whether the causative 'agent' is a virus or an enzyme." My memory may be playing a prank on me, but I seem to recollect that just three years ago you wrote in an article which was quoted all over the world, that the conclusions of Gye and Barnard provided "a solution of the central problem of cancer." These conclusions were based entirely on the belief that the same chicken tumour agent was a *virus*. If it is an enzyme, then the whole theory fails.

In the annual report of the British Empire Cancer Campaign, published on July 9th, I mentioned that I had once induced the Rous sarcoma by the injection of minced normal fowl pancreas, but I did not feel inclined to attach undue importance to it, as it was a solitary observation. It was only when my friend, Dr. Murphy, informed me of his more recent and more extensive experiments that I urged him to communicate them briefly to the International Conference on Cancer. When these are published in detail I think they will supply the information you desire.

The demonstration of the enzymic nature of the chicken-tumour agent, as you very well say, "would not in itself solve the problem of malignancy, but would rather present us with a phenomenon of far-reaching significance in its general biological aspects." My recent communication shows that I have realised this, and I can assure you, Sir, that although Dr. Murphy did not discuss it in his paper, he is well aware of the implications.

I am, Sir, yours faithfully,
ARCHIBALD LEITCH.

Cancer Hospital Research Institute, Fulham-road, S.W., July 30th, 1928.

"CARDIAC CLINICS."

To the Editor of THE LANCET.

SIR,—I shall be glad to be allowed space to comment on the letter from Dr. W. Robert F. Collis which appears in your last issue (p. 199).

1. I do not think that it should be said that in England we are apt to regard America as free from juvenile rheumatism. On the contrary, American reports and papers have been much studied here and, as their value deserved, widely quoted.

2. It is good to read of Dr. Collis's enthusiasm for special clinics for the study of rheumatic heart disease in children, but we are not, perhaps, as far behind in this matter here as he thinks. Glasgow was the first in the field, but there are now in the metropolitan area of London seven such centres (see *L.C.C. Gazette*, July 16th, 1928); and there are others, probably many others, in the provincial cities and big towns. In most cases such centres are attached to hospitals and are under the direction of one of the physicians on the honorary staff, but two of the seven London ones are under the care of Dr. Dobbie, of the L.C.C. Medical Service. As only 15 months have elapsed since the publication of the second report of the British Medical Association Committee on Rheumatic Heart Disease in Children, in which the establishment of such centres in connexion with hospitals was advocated, I think the respon the voluntary hospitals has been extremely good

3. I still hold that to call such centres "car clinics for children" is, in spite of the allu alliteration, the greatest possible mistake. As B.M.A. Committee considered, unless the w "rheumatism" is included in the title, attempt the prevention of rheumatic heart disease are bo to be handicapped. What the poor make of word "cardiac" I do not know, but certain it is hospital parents, although they may know that t child has rheumatism, hardly ever suspect presence of heart disease. For this reason mos the clinics have in England been called "rheuma supervisory centres." This tends, no doubt, to the clinic not only with "potential cardiacs," but with "potential rheumatics," yet, surely, the r way to study rheumatic heart disease in chil is in terms of the great systemic infection rather as a static disease of a single organ.

4. In a less important and personal matter, I leave to state that I have never held nor expre the view which Dr. Collis attributes to me, that " environmental factors at work (of which cold damp are the most important) must to some ex centre round the production of disease-infe tonsils." The phrase in brackets does not occu my paper, nor does it correspond with anythin my mind.

As this exaggerated view has been attributed me before in your correspondence columns militates against the success of much for which striving, I should like to add that to call atten to cold damp as a possible factor in the produc of juvenile rheumatism is no reason for my b credited (or debited) with the view that this is chief thing operating. I hold that there are a dozen predisposing factors, and where t "click" (as the saying is) there develops juv rheumatism. Of these factors, exposure to damp is one—sometimes absent, but often import

I am, Sir, yours faithfully,
Harley-street, W., July 28th. REGINALD MILLE

GLYCERINE IN THE TREATMENT OF SUPPURATIVE OTITIS MEDIA.

To the Editor of THE LANCET.

SIR,—When house surgeon to the Royal Un Hospital, Bath, in 1884, it was difficult to t satisfactorily cases of suppurative otitis media the dry dressings then in vogue, because the patients were unable to attend with sufficient r larity. Something therefore had to be found home use. I began with perchloride of mercur glycerine 1 in 1000. The results were astonish recent cases completely recovered in a few days, chronic cases after having resisted all other kn forms of treatment. The value attributed to glyce is its hygroscopic quality which permits it to se the innermost recesses of the suppurating sinuses the antiseptic dissolved in it. I mentioned treatment to my old friend, Prof. Rushton Par and we find him at the British Medical Associa meeting at Newcastle in 1893 advocating it routine treatment, on which reliance could be pla He tried carbolic acid in glycerine, which is equ good. Whether perchloride of mercury or carb acid be employed, the glycerine must be neat wit the addition of water. One case made a impression on me, that of an American who had a discharge from his left ear for 30 years. Th was a large perforation of the tympanic membr at the lower and posterior quadrant which comple healed and his hearing returned. Now, years a my retirement, I come across cases among acqua ances and friends where all treatment has been gi up in despair, but which recover under the glyce perchloride application.

I am, Sir, yours faithfully,
Charmouth, Dorset, July 24th. T. PAGAN LOW

POST-OPERATIVE MASSIVE COLLAPSE OF THE LUNGS.

To the Editor of THE LANCET.

SIR,—The importance of post-operative pulmonary complications is ably set out by Dr. C. R. Boland and Dr. J. E. Sheret in their paper on massive collapse of the lung, which appeared in your issue of July 21st (p. 111). The clinical description and the radiograms are admirable, but the explanation of the process is inadequate. If the massive collapse be due to plugging of bronchi why should it be more frequent after upper abdominal operations, why should it be entirely independent of the anæsthetic administered, why should it occur at all ages with equal frequency, and why should it be met with in cases where there is not the least suspicion of bronchitis or increased bronchial secretion?

That a plugged bronchus can cause collapse of the lung is well known; undoubted cases have been seen and described. When a large bronchus is plugged the onset is sudden—absolutely sudden—and the patient becomes immediately urgently ill and cyanosed. The lung slowly deflates, and the patient becomes gradually accustomed to his diminished oxygenating area and regains comfort. Later on he begins to expectorate, and slowly recovers his pulmonary function. The degree of deflation is never as great as that seen in the most severe cases of massive collapse, and the breath sounds over the lung with a plugged bronchus are absent even before deflation has begun. Bronchial breath sounds are not heard. This picture is a complete contrast to that given by massive collapse which follows injury or operation where the onset of symptoms is more gradual, dyspnœa appears within a few hours of the injury and gets worse, some slight duskiness may be detected, but cyanosis is seen only in the worse cases. Commonly both lungs are affected moderately, often one rather more than the other, usually the right base is the more deflated; but when one lung is affected the degree of deflation is considerable and may be complete. Respiration is quickened and shallow; on the affected side thoracic movement is limited, interspaces are indrawn during inspiration, and the abdomen is rigid. Breath sounds are weak at first, later become bronchial, and in complete deflation are absent except over the lung root.

Of the gunshot injuries which I saw during the late war I still possess records of 666 cases; of these a large number showed some bilateral deflation of the lungs; 30 showed massive collapse of one lung, and 12 had complete collapse of one lung. Among the post-mortem examinations were two on men who died (8 and 14 hours after being wounded) apparently of lung collapse. My note is a follows:—

> The lungs are extremely small, only filling about a quarter of the pleural sacs. They are blue and solid-looking. The lobes of the lower lobes sink in water, but the upper lobes are crepitant. There is no evidence of any bronchial obstruction; the bronchi do not contain blood or any excess of secretion.

Two of the most marked examples of complete pulmonary deflation which I have seen occurred in (1) a soldier shot through the upper part of the left shoulder—lung and pleura uninjured; (2) a girl of 18 who had a hemithyroidectomy under local anæsthesia. Neither of these cases showed cough or expectoration at any time.

The plugging of a bronchus is then an inadequate explanation of post-operative or traumatic collapse of the lungs because it fails to explain: (1) the common bilateral and occasional extensive unilateral deflation; (2) the gradual extension of deflation to the upper lobe of the affected lung; (3) the presence of bronchial breath sounds and increased vocal resonance in the affected lung.

As a result of my experience of examination of hundreds of men with thoracic wounds during the war, examinations which were clinical, X ray, and final at the time of operation, and, in a number of cases, post mortem; also of the examination of a considerable number of cases of lung complications following operation since the war, I suggest that massive collapse of the lung can only be explained adequately on the following theory.

1. That as a result of a stimulus applied to the body somewhere between the hyoid and the pubes (these are the limits within which in my personal experience injuries have been followed by massive collapse) a reflex constriction of bronchioles is set up.

2. That normally this reflex affects both lungs equally, and results in a decrease in the lung volume with raising of the diaphragm on both sides, and an increase in the negativity of intrapleural pressure. This condition was well seen and was very common in the wounded soldiers in France. In men who had small pleural effusions as the result of a thoracic wound the intrapleural pressure was more negative than normal in spite of the effusion, and the removal of even a few ounces of fluid during the first 48 hours after the injury was likely to be followed by cyanosis, dyspnœa, and marked thoracic pain.

3. In some cases the reflex affects only one lung, not necessarily on the side of the injury, and massive collapse results. It may be that normally the whole bronchial tree dilates slightly during inspiration and again during expiration. Failure to dilate during inspiration with normal dilatation during expiration would lead to pulmonary deflation, and if the abnormality were unilateral to marked collapse.

If we suppose that a reversal of this supposed normal mechanism is possible, so that a normal inspiratory dilatation is converted into an inspiratory constriction of bronchi while the expiratory mechanism remains normal, a far greater degree of deflation is possible. A reversal of the conditions following an injury—that is, a reflex constriction of the bronchi during expiration with normal dilatation during inspiration—may explain the phenomena of asthma, in which expiration is longer than inspiration, and lung overdistension is found.

There are many data in experimental physiology which confirm the presence and action of both dilator and constrictor muscles in the bronchi, and the condition of the lungs in guinea-pigs killed by anaphylactic shock strongly suggests the reflex constriction of bronchi. But the importance of lung collapse lies in (1) its comparative frequency after operations of the upper abdomen, (2) its liability to be the starting-point of pneumonia, (3) the means to be taken to prevent it, (4) treatment. For prevention I believe that combined regional and general anæsthesia should be most effectual.

For treatment in the most marked cases I believe that the best procedure is to introduce a small quantity of air into the pleura on the side of the collapse. This allows the diaphragm to move normally, restores the mediastinum to its median position, and relieves distress—I am, Sir, yours faithfully,

K. DOUGLAS WILKINSON.

Birmingham, July 25th, 1928.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 21st Dr. Boland and Dr. Sheret advise post-operative postural drainage of the bronchial tree, as a prophylactic of massive collapse, in other words, removal of the secretions when formed. May I suggest that a better method, and one more truly prophylactic, is to prevent the formation of the secretions? In a fairly long experience, extending over many hundreds of abdominal operations, I cannot recall a single instance in which any kind of lung complication occurred, in any case in which the preoperative condition of the lungs was normal and the peritoneal cavity not infected. Instead of the usual preoperative hypodermic injection of atropine gr. $\frac{1}{100}$ with morphia gr. $\frac{1}{6}$ to $\frac{1}{4}$, the patient (adult) is given, half an hour before the operation, an injection of atropine gr. $\frac{1}{50}$ without morphia. This makes the patient so dry that, when he reaches the theatre, he can scarcely smack his lips. This dried-up condition usually persists throughout the operation and for some hours afterwards. Very exceptionally, and only if the patient is secreting profusely, atropine gr. $\frac{1}{50}$ is

repeated, either at the end of the operation or after return to the ward. Nearly every case was anæsthetised with ether and was nursed, after operation, in the Fowler position.

I am, Sir, yours faithfully,

Plymouth, July 28th. C. HAMILTON WHITEFORD.

SMOOTH AND ROUGH VARIANTS OF BACTERIA.

To the Editor of THE LANCET.

SIR,—In a special article on this subject appearing in your issue of July 7th (p. 31), it is pointed out that many bacteriologists now recognise that there are wide adaptive fluctuations within the "species," or races, of many bacteria. Later on, however, the writer remarks that the observations of Todd [1] and Cowan [2] are inconsistent, by which I presume he means that both these authors cannot be right because the former found that the rough colonies of streptococci were more virulent than the smooth, whereas the latter found that, as in most other bacterial races which exhibit this phenomenon, the smooth streptococci were relatively more virulent than the rough. Since this is the second time within a week that I have seen the same criticism of Todd and Cowan's results, I thought that a note on one experience at Greenwich might be of general interest.

If S and R are used merely as convenient terms to denote colony appearance without any implication of antigenic structure, then diphtheria bacilli (*Corynebacterium diphtheriæ*) show well-marked rough and smooth varieties when grown on certain culture media. During the years 1922 to 1924 I collected over 100 strains of *C. diphtheriæ*. The chances among this series that an R or S strain would be toxigenic or not were about equal. There was no correlation whatever between the two pairs of characters, R and S, and virulence and avirulence. During 1927 and 1928 nearly 200 strains of *C. diphtheriæ* were isolated from the same school and were examined for R and S qualities and toxigenicity by my co-worker, Surgeon-Commander Parker.[3] The R strains were all avirulent, without any exception, the S strains only produced five avirulent cultures. In this series, therefore, R was always correlated with lack of virulence while S forms were almost invariably virulent to guinea-pigs. I think this evidence, in the lack of any further information, would have been considered good enough by many workers to conclude that the rough variants of *C. diphtheriæ* were always atoxic. The evidence might have led me into such a mistake, but for my past experience and the fact that Parker examined a further 50 strains of *C. diphtheriæ* collected from the environment outside the school. This last series of cultures showed no significant agreement between these characters, the R and S varieties containing both virulent and avirulent strains. These investigations show that, in as distinct a "species" of bacterium as it is practicable to define, two characters could at one time be completely correlated, while in *the same place* at another time the same characters would show no significant correlation. Similarly in one environment, correlation was complete while at *the same time* in a different environment there was no agreement between the same sets of character.

The variability of bacteria is of such fundamental importance in medicine that two further recent observations bearing on this subject are worth noting. Whittle,[4] in a recent paper, makes a praiseworthy attempt to discover a reliable method of distinguishing pneumococci from streptococci. After confessing there are certain discrepancies between his results and that of other workers in the same field, he found bile solubility to be the most reliable criterion by which to recognise a pneumococcus. But after finishing his paper he had the bad luck to find a completely bile-insoluble Type I. pneumococcus which had to be put in a footnote. By a striking coincidence in the number of the journal which contained the pre reference, Griffith[5] describes a fully virulent R va of pneumococcus, the only exception he had fou his extensive experience, to the rule that R strai pneumococci are relatively avirulent to mice compared with S. Here were two "laws" v seemed inviolate until the exceptions turned After our experiences at Greenwich it is conce if Whittle or Griffith were to repeat their work different country or in 10 to 50 years' time exception might have become the rule and the the exception! Hence there is no necessity to sider such observations as those of Todd and C to be mutually incompatible, especially as investigators only used a very small numbe strains of streptococci in their experiments.

The very fact that there are so many appa inconsistencies in bacteriological literature w indicate that incongruities are just as often du bacterial variability, as to errors or differenc technique which is the explanation some bact logists still seem to prefer. The bacteria as a g are the most plastic of living organisms, and different races fluctuate round a conventional sp type. It is one of the most important and diff tasks of modern bacteriology to define the limits, estimate the rapidity, of these adaptive fluctua and to try to discover the environmental sti which produce them. Griffith's work, just referre is a brilliantly original attempt to do this in the of pneumococcal types, whether his results are confirmed or not. We cannot be reminded frequently that the "species concept" applie bacteria is far less definite than when applied t sexual metazoa. As long ago as 1912 Minchin [6] uncertain if "species," in the strict biological mea occurred among the bacteria at all. Although I w not go as far as that, yet these doubts of an emi worker in pure biology are a salutary subject fo worker in applied medical biology to ponder ov

I am, Sir, yours faithfully,

SHELDON F. DUDLE

Royal Naval College, Greenwich, July 26th, 1928.

CANCER AND DIET.

To the Editor of THE LANCET.

SIR,—On p. 192 of your last issue a speaker at recent Cancer Conference is reported as saying "a campaign had been going on amongst the me profession that certain forms of food produced ca An eminent surgeon was even devoting his lif persuading the public that cancer was due to ea meat." As chairman of the Food Committee of New Health Society and therefore closely conne with its dietetic propaganda, may I state that no s absurd statement has ever been issued by the Soc or by its president. The ultimate damage that accrue from long continued malnutrition and o results of a faulty diet may, in the opinion of som us, help to explain the cancer problem. This theory that the public, at any rate, will be advised to ponder and act upon.

I am, Sir, yours faithfully,

S. HENNING BELFRAG

New Health Society, London, July 31st, 1928.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to e member of the medical profession. If the form not been received, a duplicate will be sent on requ We shall be grateful for the return of the forms an early post.—We are, Sir, yours faithfully,

J. AND A. CHURCHILL

Obituary.

R ARTHUR CHANCE, F.R.C.S. & P. IREL., HON. F.R.C.S. EDIN.,

AST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

E regret to announce the death of Sir Arthur nce, which occurred at his residence, Merrion- are, Dublin, on July 26th, after a long illness, the age of 69 years. He had been for many s one of the most prominent members of the ession in Ireland and his death will be regretted a large circle of patients and friends.

orn in 1859, son of Albert Chance, of Dublin, received his education in Dublin and ob- ed diplomas from the two Royal Colleges in 8), and at once devoted himself to surgery.

SIR ARTHUR CHANCE.
Photo by Lafayette.

Whilst a very young man he was appointed surgeon to Jervis-street Hospital, and a few years later moved to the Mater Misericordiæ Hospital, with which he remained connected for the rest of his life. He took an active part in the work of the Council of the Royal College of Surgeons, of which College he was elected President in 1903. For many years past he has represented that body on the General Medical Council last year was nominated as its representative the Medical Registration Council of the Irish e State, a post which, however, he had speedily resign on account of ill-health. From 1917 to 0 he was Inspector of Military Surgical Hospitals Ireland, with the rank of colonel in the Army lical Service. He filled a term as President of Royal Academy of Medicine in Ireland, and was geon to more than one Viceroy of Ireland, so that n in 1905 he received the honour of knighthood distinction had been anticipated for him by all knew him. There were few public professional vities in Ireland in which he did not take an ve share. Specially interested in education, he e very useful service to the General Medical ncil, while he was determinedly opposed to any nge in the system of medical registration after establishment of the Irish Free State.

hance was a man of great versatility and quick- s of intellect, who would have been successful in profession he might have chosen to adopt. His dent leadership and shrewd judgment will long be sed, and he will be remembered as having played important part in Irish affairs at a time of special iculty.

Ie married, first, Martha, daughter of Daniel ney of Belfast, and secondly, Eileen, daughter of liam Murphy, of Dartry, who survives him with t sons and five daughters. Three of his sons are nbers of the medical profession, one, Mr. Arthur nce, being surgeon to Dr. Steevens' Hospital, blin.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—Diplomas of L.R.C.P. and M.R.C.S. have been conferred upon 167 candidates (136 men and 31 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the by-laws of the Colleges. The following are the names and medical schools of the successful candidates :—

G. Allen, Birmingham and London ; J. M. Anderson, Durham and Charing Cross ; W. R. Ashby, Cambridge and St. Bart.'s ; Julia C. H. Avery, St. Mary's ; Gertrude C. Banks, Royal Free ; S. Behrman, St. Bart.'s ; W. A. G. Bell, Cambridge and St. Thomas's ; A. Bennett, St. Bart.'s ; Mary Berkeley, Royal Free ; T. H. Berrill, Bristol ; S. P. Bhatia, Bombay and St. Thomas's ; C. H. Birt, Birmingham ; F. A. Blackwood, St. Thomas's ; Kathleen L. Bland and J. R. Bond, Univ. College ; V. G. Morgaonkar, Bombay and London ; N. J. Boulton and R. V. Bradlaw, Guy's ; J. V. Broad, Cambridge and St. George's ; Nellie Brown, Westminster ; E. C. B. Butler, London ; Beatrice A. Butterworth, Royal Free ; E. N. Callum, London ; Catherine F. Cameron, Cambridge and Royal Free ; L. A. Canaan, Yale and London ; Mavis H. D. Carr, Cambridge and Royal Free ; T. H. Carr and B. R. Caygill, Leeds ; Muriel G. E. Clark, Charing Cross ; W. A. Clements, Sheffield ; Nellie Clifton, Royal Free ; Lilian M. C. Clopet, Cardiff ; Dorothy M. Conyers, Royal Free ; T. M. Corcoran, Univ. College ; O. J. C. Cotton, Cambridge and St. Thomas's ; E. Courtin, St. Thomas's ; J. H. Crawford, Cambridge and St. Mary's ; A. T. Croucher, St. Mary's ; A. M. Cunningham, Cambridge and Univ. College ; D. W. Currie, Leeds ; T. Dagger, Liverpool ; A. Danin, Guy's ; H. W. Daukes, St. Thomas's ; W. P. M. Davidson, St. Bart.'s ; E. L. F. De Mel, Ceylon ; W. F. de Villiers, Cape and London ; P. Dickman, Cape and Charing Cross ; C. J. V. Dobbin, Guy's ; G. H. Dobney, Middlesex ; J. F. Duesbury, Birmingham ; J. W. Ellis, Guy's ; R. C. S. Evans, Cardiff ; A. C. Fisher and Cecilia F. Fox, Bristol ; P. H. Fox Cambridge and St. Bart.'s ; E. Fulford, Guy's ; G. H. Garfield, Cardiff ; R. J. S. Garrow, St. Thomas's and Leeds ; F. W. Gilbert, Guy's ; Agnes G. Gillespie, Liverpool ; Y. Gimpelson, Royal Free and St. Mary's ; L. Godlove, Leeds ; S. Goldman and J. P. Gubbins, London ; J. C. Heather, Guy's ; Kathleen M. Henderson, Laurel K. Heny, Helen M. Herbert, and Alice D. M. Hodge, Royal Free ; F. E. G. Hopkins, Cambridge and Guy's ; D. R. House, Bristol ; I. M. Hughes, Manchester ; E. A. Hunter, London ; M. Jafar, Punjab ; M. K. Jilani, Lahore and Liverpool ; A. W. Johns, London ; S. Kaul, Punjab and St. Bart.'s ; G. H. Kennett, Sydney ; B. Kettle, St. Bart.'s ; G. G. King, Madras and St. Mary's ; M. L. Kreitmayer, St. Bart.'s ; Nellie I. Lanckenau, Royal Free and Univ. Coll. ; Kenneth E. Lane, Guy's ; T. C. Larkworthy, Cambridge and St. George's ; E. G. Laurence, St. Bart.'s ; R. R. Leaning, St. Mary's ; J. C. Leigh, Leeds ; G. Leighton, Birmingham ; G. E. Lewis, Cambridge and London ; I. B. Limbery, St. Thomas's ; Kathleen M. MacLaren, Westminster ; G. C. C. MacVicker, Cambridge and St. Bart.'s ; M. J. Malley, St. Bart.'s ; F. B. Mallinson, St. George's ; H. M. Mikhail, Univ. College ; Hermia M. Mills, Royal Free ; L. Milner, S. Africa and Guy's ; W. E. S. Moreton, Charing Cross ; R. H. Morley, Leeds ; I. Morris, Univ. College ; L. H. Morris, Cambridge and London ; O. N. Morris, King's College ; J. E. Morton, Guy's ; Millicent Moseley, Birmingham ; J. H. Moynihan, Charing Cross ; Bhavani Natarajan, Bombay ; L. A. Newton, St. Bart.'s ; H. G. Nimbalker, Bombay and Middlesex ; G. P. Nixon, St. Bart.'s ; G. W. Oliphant, Guy's ; E. G. M. Palser, Univ. College ; A. W. Patton, St. Bart.'s ; Margaret E. Peaker, King's College ; M. G. Pearson, Oxford and Westminster ; A. L. P. Peeney, Manchester ; R. L. P. Peregrine, Oxford and Guy's ; F. Phillips, Adelaide and London ; J. A. Pocock, Cambridge and Univ. College ; H. G. Pritchard, Oxford and Charing Cross ; N. L. Probert, Cardiff and Middlesex ; A. Rabinowitz, Berlin and Middlesex ; R. H. Raine, Durham ; R. J. H. Raines, Leeds ; E. A. P. S. Rawlings, Charing Cross ; R. G. E. Richmond, St. Thomas's ; D. T. Robinson, Manchester ; J. B. Robinson and W. P. Roe, Guy's ; M. V. Samuel, Adelaide and London ; Eluned Saunders, Cardiff and Westminster ; Christine F. T. Saville, Univ. College ; E. H. Sears, Guy's ; H. M. Sein, Calcutta and Guy's ; H. Selby-Brown, Guy's ; H. T. Simmons, Manchester ; W. H. Simonds, Cambridge and St. Thomas's ; D. Sivasubrahmaniam, Madras and London ; Constance B. Smith, King's College ; Edith J. L. Smith, Royal Free ; Elizabeth S. Smith, Birmingham ; E. H. Spickett, St. Bart.'s and Cardiff ; T. T. Stamm, Guy's ; D. M. Stern, Cambridge and London ; R. Ström-Olsen, Cardiff ; A. B. Sullivan, Sydney and London ; A. B. Taylor, Birmingham ; J. G. Thwaites, St. Thomas's ; B. Timothy, Madras and London ; W. E. Tucker, Cambridge and St. George's ; G. N. Unnithan, Madras and Univ. College ; B. T. Utley, St. George's ; L. E. Vine, Bristol ; F. H. Ward, Cambridge and St. Bart.'s ; D. K. Weston, Guy's ; D. B. J. Wijeyesekera, Ceylon and King's College ; P. Wiles, Middlesex ; Gladys E. Wilkinson, Manchester ; G. G. Willcox, Cambridge and St. Thomas's ; Enid M. Williams, Cardiff ; L. D. Williams, Cardiff and Guy's ; W. A. Wilson, Univ. College ; E. W. Winch, Cambridge and St. George's ; H. S. H. Wood, Middlesex ; J. L. M. Wood, Sheffield ; Elsie E. Wright, Royal Free and St. Mary's ; T. C. Yip, St. Bart.'s ; and H. D. R. Zscherpel, Madras and St. Bart.'s.

The undermentioned diplomas were conferred (jointly with the Royal College of Surgeons) upon the following candidates :—

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.

C. H. Ackroyd, C. H. Bamford, W. J. Chapman, A. L. El Kirdani, Charlotte E. Fisher, B. B. Ghosh, J. B. Hamilton, R. J. Harley-Mason, D. R. Jadeja, D. Katz, G. L. Khirwadkar, D. G. Kotibhaskar, F. J. Lavery, H. H. Mahmood, T. M. O'Neill, F. W. G. Smith, A. F. Stewart, J. M. Thomson, A. Walbank, and J. Wood.

DIPLOMA IN PUBLIC HEALTH.

D. R. Bernhardt, R. A. D. J. Bernhardt, H. P. Bilimoria, H. St. C. Colston, A. C. Counsell, G. I. Davies, C. H. Dhala, M. Farid, F. Harris, G. H. Hayes, Margaret Holdsworth, D. R. Jandial, Iris A. Jenkin-Lloyd, Eva M. Malmberg, S. N. Michaels, Josefine W. Nagel, M. A. Nicholson, F. W. Oldershaw, D. B. Parakh, Jessie L. Robb, Mary Schofield, Beatrice M. Smithies, Josephine I. Terry, D. L. Tucker, and G. R. Waller.

Diplomas in Laryngology and Otology and in Psychological Medicine have been conferred upon candidates whose names appeared in our issue of July 21st (p. 153).

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an ordinary meeting of the College held on July 26th, with Sir John Rose Bradford, the President, in the chair, the following were elected members :—

Charles N. Armstrong, Ramananda Bandyopadhyay, Philip Bayer, John L. Edwards, Frank R. Fletcher, Robert D. Gillespie, Frank Goldby, Hamilton Hartridge, Thomas R. Hill, Horace Joules, Charles E. Kellett, Robert M. B. Mackenna, Patrick H. O'Donovan, Ian H. K. Stevens, and Arthur S. Wesson.

Licences to practise medicine were conferred on 167 candidates whose names appear above.

Mr. Arthur Sturgess Hollins, M.B. Camb., M.R.C.P., of King's College Hospital, was awarded the Murchison Memorial Scholarship.

The following officers of the College, members of committees, and examiners were elected for the ensuing year :—

Censors.—Lord Dawson of Penn, Dr. J. S. Collier, Dr. A. P. Beddard, and Dr. R. A. Young.
Treasurer.—Dr. S. P. Phillips.
Registrar.—Dr. Raymond Crawfurd.
Harveian Librarian.—Dr. Arnold Chaplin.
Assistant Registrar.—Dr. R. O. Moon.
Library Committee.—Dr. F. Parkes Weber, Dr. H. C. Cameron, Dr. H. R. Spencer, and Dr. C. J. Singer.
Curators of the Museum.—Dr. J. M. Bruce, Dr. C. E. Lakin, Dr. William Hunter, and Dr. J. H. Thursfield.
Finance Committee.—Dr. H. Morley Fletcher, Sir John Broadbent, and Dr. J. H. Thursfield.
Examiners.—Chemistry : Mr. H. W. Cremer and Mr. W. H. Hurtley. Physics : Mr. J. H. Brinkworth and Mr. D. Orson Wood. Practical Pharmacy : Dr. W. J. Adie, Dr. Hugh Gainsborough, Dr. Newman Neild, Dr. V. J. Woolley, and Dr. Orlando Inchley. Physiology : Dr. B. J. Collingwood and Dr. Swale Vincent. Anatomy : Dr. G. Elliot Smith. Pathology : Sir Frederick Andrewes and Dr. Charles Bolton. Medical Anatomy and Principles and Practice of Medicine : Sir Percival Hartley, Dr. A. G. Phear, Dr. Herbert French, Dr. A. E. Russell, Dr. Cecil Wall, Dr. J. A. Nixon, Dr. Frederick Langmead, Dr. C. E. Lakin, Dr. D. H. de Souza, and Dr. F. M. R. Walshe. Midwifery and Diseases Peculiar to Women : Dr. Cuthbert Lockyer, Dr. Eardley Holland, Dr. Malcolm Donaldson, F.R.C.S., Dr. William Gilliatt, and Dr. Stanley Dodd. Public Health : Part I., Dr. J. H. Ryffel ; Part II., Dr. Charles Porter. Tropical Medicine : Dr. J. C. G. Ledingham and Dr. H. H. Scott. Ophthalmic Medicine and Surgery : Dr. Grainger Stewart. Psychological Medicine : Part I., Dr. Edward Mapother ; Part II., Dr. J. Porter Phillips and Dr. Bernard Hart. Laryngology and Otology : Dr. D. R. Paterson.

Sir Humphry Rolleston was re-elected as representative on the Executive Committee of the Imperial Cancer Research Fund.

Sir Wilmot Herringham was appointed to deliver the Harveian Oration, and Dr. J. A. Arkwright, F.R.S., the Bradshaw Lecture in 1929. The following further appointments were announced : Dr. G. F. Still as Fitzpatrick Lecturer for 1929 ; Dr. R. A. Young as Lumleian Lecturer for 1929 ; Dr. E. B. Verney as Goulstonian Lecturer for 1929 ; Dr. F. M. R. Walshe as Oliver-Sharpey Lecturer for 1929 ; The Rt. Hon. H. A. L. Fisher as Lloyd Roberts Lecturer for 1929 ; and Sir Charles Martin as Croonian Lecturer for 1930.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates for the Triple Qualification have been approved and have been admitted as Licentiates :—

FINAL EXAMINATION.

Betty C. Hamilton, E. A. Downes, John Campbell, D. A. Herd, A. J. A. Gray, Oscher Stern, J. L. Dudgeon, C. V. Salisbury, S. K. Pillai, M. J. S. Pillai, A. M. D'Cotta, Maud Heaton, H. S. Lawrence, A. F. B. Mackay, A. El Sayed El Khishin, A. B. Mendis, Robert Rajaretnam Tamber, N. S. Fraser, C. L. X. S. Muttukumaru, I. M. Chi[illegible] A. M. Fraser, David Bendel, Barney Schulman, F. [illegible] Stewart, Harry Lazarus, H. M. C. de Silva, B. S. [illegible] E. H. B. Gooch, W. D. Alvis, Aaron Jacor[illegible] R. A. F. M. Saunders, A. J. F. Almeida, F. A. Silv[illegible] J. S. Goonting.

The following have satisfied the examiners in the [illegible] mentioned subjects :—

Medicine.—J. T. F. Pearse, J. H. Brush, D. N. Chi[illegible] H. A. Mohamed, Gerald Kahn, Hope Lazarus, [illegible] Abeyaraine, Chrysostom Joseph, Leslie Myers, A. [illegible] Attia, S. S. Nagi, and Hyam Saacs.
Surgery.—J. R. Martin, J. T. F. Pearse, Hanna Bar[illegible] J. H. Brush, C. H. Wilkie, C. Joseph, Leslie Craig, Ok[illegible] Ajibade, A. L. Malik-Mansour, A. K. M. Attia, [illegible] Craig, and Kandiah Kanagasabapathy.
Midwifery and Gynæcology.—J. R. Martin, F. R. [illegible] Kennedy, Hanna Barsoum, B. A. D. Robert, M. A. Moh[illegible] John Elliott, W. P. B. Winston, Leslie Craig, T. R. Ja[illegible] Leslie Myers, S. W. Cruickshank, D. S. McMillan, Do[illegible] Brink, and Hyams Saacs.
Medical Jurisprudence and Public Health.—M. C. S[illegible] W. O. Molander, F. R. B. H. Kennedy, W. P. Ker[illegible] G. G. Brown, H. G. THOMAS'S HOSPITAL.—A tation on behalf of the governors and medical staff Thomas's Hospital, London, has been made to Mr. Roberts, C.B.E., who is now retiring from the position retary and receiver, which he has held for the last ars. Mr. Roberts's successor will be Lieut.-Colonel B. Irwin, D.S.O., who has been assistant secretary 1922.

E LATE DR. G. O. MCKANE.—Dr. George nt McKane, who died at Cleethorpes on July 26th eighty-first year, had spent nearly half a century in al practice. He gained the Scottish triple qualifica- n 1875, and retired only three or four years ago. The years of his active life were lived at Waltham, near by, where he carried on a large country practice. s also medical officer of health to the Grimsby Rural t Council, and poor-law medical officer and public ator to the fourth district of the Grimsby Union. n of strong and cheerful personality he had great s of sympathy, and enjoyed the confidence of his ts to a remarkable degree. Dr. McKane was a native xham, and before studying medicine qualified as a st. He was for many years in practice at Byers , Co. Durham, and Leeds. His two sons are members medical profession.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Bills Advanced.

IN the House of Lords on Friday, July 27th, the Reorganisation of Offices (Scotland) Bill was read the third time. In the House of Commons the Food and Drugs (Adulteration) Bill was read the third time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 25TH.

Ex-Service Man and Sleepy Sickness.

Sir HENRY COWAN asked the Secretary of State for War whether his attention has been called to the case of Alfred Lines (whose blue medical sheet was endorsed Fit for service in any part of the world), who joined the Middlesex Regiment on June 4th, 1926, served with the Shanghai defence force in China until afflicted with sleepy sickness, returned to England and was discharged from Netley Hospital as physically unfit for any form of military service on Nov. 11th, 1927, with a sum of £1, and who, after waiting for his official discharge papers, received a communication from Chelsea Hospital, dated Dec. 5th, 1927, stating that he was not entitled to any discharge pension and offering him a gratuity of £6 only, less deduction of any advances that had been made to him; and whether, having regard to the fact that his panel doctor had certified that Lines would never be able to work again and that the symptoms of the disease which necessitated his discharge from the Army first appeared during his military service with the Shanghai defence force, he would consider granting this man some compensation more adequate than the amount of 7*s.* 9*d.* actually paid him as the balance of the gratuity of £6.—Mr. DUFF COOPER (Financial Secretary to the War Office) replied: This case has been carefully reviewed at the War Office, and the Army medical authorities are satisfied that the disability was not caused by military service. In the circumstances, Mr. Lines has no claim to compensation, and the small gratuity awarded is the appropriate grant in his case.

Replying to further questions in regard to Mr. Lines's case, Mr. Duff Cooper said the War Office could not allow the principle to be established that anybody who happened to fall ill while on military service should by that fact alone be entitled to some compensation. There was no evidence to show that this man's illness was in any way connected with his being sent abroad. It was not an illness to which soldiers were subject through their being sent abroad.

Health of the Merchant Service.

Dr. VERNON DAVIES asked the President of the Board of Trade if he would consider the advisability of coöperating with the Minister of Health to issue an annual report on the health of the merchant service, bearing in mind that the seaman's mortality from disease exceeded the average by 48·8 per cent., and his mortality from violence by 4·30 per cent.—Mr. HERBERT G. WILLIAMS (Parliamentary Secretary to the Board of Trade) replied: My right hon. friend will consult the Minister of Health with regard to the suggested preparation of an annual report on the health of the merchant service, and I will let my hon. friend know the result in due course.

Tuberculosis Mortality-rate.

Sir ROBERT THOMAS asked the Minister of Health whether he was aware that there had been since 1910 little reduction in the tuberculosis mortality-rate for males between the ages of 15 and 25, while for females between these ages the rate had increased; and what measures he proposed to take to improve the position.—Sir KINGSLEY WOOD replied: The answer to the first part of the question is in the affirmative, but the rate for both males and females between these ages appears at the present time to be decreasing. The discrepancy between the rate of decrease in the mortality from tuberculosis in the general population and that in the groups referred by the hon. Member has been under consideration in my department, but my right hon. friend is advised that its causes are obscure. Investigation is proceeding, and the tuberculosis officers of local authorities will be asked to give special attention to the question.

THURSDAY, JULY 26TH.

Treatment of Casual Paupers.

Mr. SHEPHERD asked the Minister of Health whether, in view of the number of unemployed men and women now tramping the roads in search of employment, he proposed to revise the regulations concerning their treatment, with special regard to food, sleeping, medical inspection, searching, task work, detention, washing, and method of obtaining

admission.—Mr. CHAMBERLAIN replied: No, Sir. I am not aware of any reason for the revision of the regulations in force, which do, as the hon. Member is aware, make special provision for casuals genuinely in search of employment. I think it is important that there should be general and complete compliance with the regulations, and I am giving my officers further special instructions to impress upon guardians and their staffs the necessity of securing this full compliance in cases in which there is any default.

Shortage of Water in Derbyshire.

Mr. DUNCAN asked the Minister of Health whether he was aware of complaints of the short supply of water for domestic purposes in the parish of South Normanton, in the Blackwell rural district council area, Derbyshire; whether this shortage covered a period of years; whether complaints had previously been made to the Ministry of Health; whether the local authorities had laid any proposals before the Ministry for approval, and whether there was any delay occasioned in his department in this matter; and whether he was prepared to take immediate action with a view to terminating the present shortage and providing the area with a full supply sufficient for the general health and domestic needs of the inhabitants.—Mr. CHAMBERLAIN replied: The answers to the first four parts of the question are in the affirmative, and to the sixth part in the negative. In reply to the fifth part, an outline of a joint scheme was submitted to me in April, 1927, and provisionally approved in January last, but in the meantime further difficulties have arisen in connexion with the risk of subsidence. In reply to the seventh part of the question, I have directed one of my inspectors to make a local investigation with a view to expediting temporary relief, and I am hoping to receive from the local authorities concerned definite proposals for a permanent scheme on satisfactory lines.

New Cancer Hospital in Manchester.

Sir THOMAS WATTS asked the Minister of Health if his attention had been called to the proposed establishment of a cancer hospital in Palatine-road, Withington, a residential district of Manchester; and, having regard to the depreciation in the value of property in the district which would result, would he set up an inquiry into the matter.—Mr. CHAMBERLAIN replied: The answer to the first question is in the negative. If, as I assume, the reference is to the establishment of a voluntary hospital, I am not aware that it is open to me to take any action.

Traffic Noises in Urban Streets.

Sir ROBERT THOMAS asked the Home Secretary whether he was aware that there is a growing volume of public protest against the noise of urban streets; that it was endangering the lives of sick people and undermining the fitness even of those in normal health; that it interfered with education and lowered the efficiency of business; that experts estimated that 60 per cent. of the noise was preventable; and that it would continue to increase unless action was taken; and whether he would, in conjunction with the Ministers of Health and Transport, make an effort to deal with these conditions.—Sir W. JOYNSON-HICKS replied: I am aware that there is much complaint, and I think with good ground. I have done all in my power to see that the nuisance is abated, so far as this is possible, by police action under existing powers, and I will certainly consult with my right hon. friends as to whether anything further can be done.

Sir R. THOMAS: Is the right hon. gentleman aware that a high medical authority at a meeting of the British Medical Association last week estimated that the loss in efficiency to the nation owing to these noises amounted to no less a sum than £1,000,000 a week?

Sir W. JOYNSON-HICKS: Yes, I have noticed that.

Lieut.-Commander KENWORTHY: Will the right hon. gentleman consult with the Prime Minister about this in view of the probability that the present laws are insufficient to deal with the growing noises?

Mr. LANSBURY: Will the right hon. gentleman communicate with the London County Council and ask them to keep the tramway tracks in order and thus prevent the most infernal noises?

Sir W. JOYNSON-HICKS: I will communicate with the Minister of Transport whose duty it would be, I think, to communicate with the London County Council.

Captain CROOKSHANK: Will the right hon. gentleman look into the practice which obtains in the United States of zoning certain areas where certain noises are prohibited?

Sir R. THOMAS said that this was a fearfully important question, and he thought that the House ought to get from the Home Secretary something more than they had had. The right hon. gentleman had said that he would consult with his Ministerial colleagues. Could he do so and report to the House before the end of the session?

Sir W. JOYNSON-HICKS said that he would take the opportunity of discussing the matter with his colleagues, but whether it would be possible to answer a definite q before the end of the session he could not say.

Conjunctivitis in the Artificial Silk Industry.

Mr. KELLY asked the Home Secretary whether had been received from his inspectors about the i in injuries suffered by men and women engaged artificial silk industry.—Sir WILLIAM JOYNSON replied: I have received reports by the inspectors I am glad to state show that, except in one works there has been a large increase in the number of employed, the number of cases of conjunctivitis has, recent months, been decreasing. As the hon. M knows, this industry is receiving the closest attentic from the staff generally and from the medical insp and much has been, and is being, done to impro conditions.

Early Treatment of Mental Disease.

Dr. VERNON DAVIES asked the Minister of Healt was aware that the only hope of reducing the incid insanity and improving the recovery-rate was by the law so as to allow and encourage the early and treatment of persons mentally ill; and if he would, early date, give this matter his serious considerati take the necessary action.—Mr. CHAMBERLAIN repl should be sorry to think that the *only* hope of reduc incidence of insanity and improving the recovery-r in the measures which my hon. friend suggests. fully realise the great importance of improving the f for early mental treatment, and as I have frequently I hope to be able to take the necessary action as soo is practicable to introduce legislation.

Regional Medical Officers and Drug Prescriptions.

Mr. SHORT asked the Minister of Health wheth special sum was allocated for the payment of dru scribed by panel doctors; whether he was awar regional medical officers had recently brought pressur panel doctors respecting their prescriptions and t limiting their discretion in prescribing medicines for patients, and that the East Sussex Insurance Com at its meeting on July 3rd, expressed its view that a tioner should not cease to prescribe drugs which he b to be reasonably necessary for the adequate treatm panel patients; and if he would explain the nature instructions given to regional medical officers o matter.—Mr. CHAMBERLAIN replied: As regards th part of the question, I would refer the hon. Member reply given to a question on April 4th. I am aware views expressed by the East Sussex Insurance Com The duty of insurance practitioners is to prescribe and sufficient medicines, and the purpose of the inte arranged between certain practitioners and regional m officers is solely to secure that this duty is performe

MONDAY, JULY 30TH.

Welsh Board of Health.

Mr. JOHN asked the Minister of Health if the reas the change in the composition of the promotion bo the office of the Welsh Board of Health was due alleged internal difficulties; and whether he had re complaints with regard to the action of the pro board in recommending promotions.—Mr. CHAMBE replied: The answer to both questions is that troul regard to promotion have been part of the interna culties of the past, and that the change in question to me the best way of securing a better position future.

Analysts and Food and Drugs Adulteration Bill.

Mr. CECIL WILSON asked the Minister of Health wh in regard to the Food and Drugs (Adulteration) Bil consultation had taken place with the Institute of Chen or the Society of Analysts, or other similar bodies; a not, for what reason.—Mr. CHAMBERLAIN replied: N As the object of the Bill is not the amendment bu consolidation of the existing law, its preparation purely legal matter, and it was not considered necess consult the bodies mentioned. I understand, hov that the Society of Public Analysts communicated wit Joint Committee on Consolidation Bills, and tha Committee considered the Society's views on the Bill.

Sewage Effluvia and Public Health.

Mr. LOOKER asked the Minister of Health whether h aware that the effluvia coming from the sewage di works of the West Kent Sewerage Board constitu menace to the health of the inhabitants of the par West Thurrock; and if he would take steps in the mat Mr. CHAMBERLAIN replied: I am not aware that th any menace to health from this cause. I understand officials of the District Council and the Sewerage have been conferring on the subject and I am ascert the position.

TUESDAY, JULY 31ST.

Use of Preservatives in Cream.

. THOMAS KENNEDY asked the Secretary of State for and if he had considered any representations made to by the distributors of fresh cream in Scotland regarding oss involved in the observance of the regulations biting the use of preservative in cream ; if he was aware arge quantities of cream sent daily from the creameries nfit for use before it reached its destination ; that as sequence tinned foreign cream was rapidly taking the of home-produced double fresh cream in the Scottish et ; that the foreign cream was inferior in food value ; efore the passing of the present regulations a harmless minute quantity of boron preservative was allowed, was sufficient to keep cream in perfect condition for days or more ; and if he would now consider the desira- of suspending the regulations referred to.

. WESTWOOD asked the Secretary of State for Scotland had received any communication from the distributors sh double cream drawing his attention to the effect e prohibition of the use of 0·04 per cent. of boron vative in cream ; and, if so, what action, if any, he sed in the interests of farmers, distributors, and the al public.—Sir J. GILMOUR replied : Representations e various points mentioned in the questions have been ed but, for reasons which I have already given, I am repared to suspend the operation of the Preservative lations in regard to double cream. This matter has long and carefully considered and the Scottish Board alth are satisfied that if proper attention is given at ages to the production of milk and the handling and t of cream it ought to be possible to market fresh e cream in a sound condition. In regard to the sug- n that the amount of preservative added to double before the regulations came into operation was ess and minute, I would point out that the amount was 0·4 per cent., and that the Departmental Com- on Preservatives reported against the use of boric n foodstuffs in the interests of public health. So far ncerns the interests of farmers, the National Farmers of Scotland and the Scottish Agricultural Organisa- ociety have passed resolutions in favour of the pro- n of preservatives in cream.

Short Measure in the Sale of Milk.

. LOUGHER asked the President of the Board of Trade er, in respect of the sale of milk, he could state the of the delay in issuing regulations to enable adequate l to be maintained in connexion with methods of milk bottles ; and whether he was satisfied that the were at present adequately guarded against short re being supplied.

onel ENGLAND asked the President of the Board of if he was now operating the section of the Weights leasures Act which prescribed the use of milk bottling measuring machines ; if so, when this section of the ecame operative ; and what steps had been taken to it out.—Sir P. CUNLIFFE-LISTER replied : There is t of Parliament which prescribes the use of milk g and measuring machines, but draft regulations ng to such machines the general provisions of the ts and Measures Acts are now under consideration small committee representative of local authorities ther interests concerned. I hope to be able to issue aft shortly for public information. In the meantime ovisions of the Sale of Food Act, 1926, which makes offence to give short measure, are available for the tion of the public.

Grants for Supply of Milk and Nourishment.

. THURTLE asked the Minister of Health the total t of economy in Exchequer expenditure he expected ct by his proposals to local authorities to cut down grants for the supply of milk and nourishment in ion with maternity and child welfare work.—Mr. BERLAIN replied : It is estimated that the total amount Exchequer grants payable to local authorities in t of their expenditure for this purpose during the t financial year will be about £12,000 less than would been the case in normal circumstances.

Sun Helmets for Police Constables.

t.-Commander KENWORTHY asked the Secretary of for the Home Department if he would consider the f an approved type of sun helmet, especially to con- employed on traffic control in the middle of the during hot weather.—Sir W. JOYNSON-HICKS replied : uestion has been considered, but our summers are so short and changeable that it has not hitherto hought necessary to provide any special sun or straw s. When the weather is hot, orders are given for the al of chin straps, and if the heat continues the question further considered.

Vacancies.

DEATHS.

CHANCE.—On July 26th, in Dublin, Sir Arthur Chance, F.R.C.S.I., F.R.C.P.I., F.R.C.S. Edin., in his 70th year.

CURD.—On July 27th, at Forbes Fraser Hospital, after two days' illness, Charles Curd, M.R.C.S., L.S.A., of Gay-street, Bath.

LEES.—On July 22nd, at Breifond, Boyne Park, Tunbridge Wells, Charlie Lees, M.R.C.S., L.R.C.P., L.D.S. Eng., aged 53.

*N.B.—A fee of 7*s.* 6*d.* is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

HERPES ZOSTER AND CHICKEN-POX.

CASES are always being reported in which herpes zoster and chicken-pox appear in the same household, or in which people develop varicella after being in contact with herpes zoster, and vice versa. The isolated examples must now number many hundreds and constitute a formidable obstacle to the dualists who maintain that there is no inherent connexion between the two conditions. J. von Bókay, in 1892, was the first to suggest a common ætiology, and much evidence in its favour has since been adduced. Dr. G. A. Esquier, for instance, has just described a case in which the two conditions appeared simultaneously.[1] The patient was a soldier of 21, who did not report sick until the fourth day of his attack of chicken-pox, when fever and, more particularly, severe pain in his left side, took him to hospital. At that time typical vesicles in all stages of development were found on the scalp and body and—more sparsely—on the face, neck, and buccal mucosa. There were none on the limbs nor on the left side, where the pain was, and on this area typical herpes zoster developed along the seventh intercostal nerve. The zona consisted of vesicles of varying maturity, the youngest being at the end of the nerve, and the oldest near its root. The number of lymphocytes in the cerebro-spinal fluid proved to be 28 per cubic millimetre, and the differential white cell count in the blood showed 42 per cent. of lymphocytes and only 15 per cent. of polymorphonuclear leucocytes. As the crusts fell off, the blood count returned towards normal. Dr. Esquier explains this case by assuming that the virus of varicella can be fixed either in the skin, or in the spinal ganglia, or in a segment of the cord, producing, respectively, an attack of chicken-pox, a herpes zoster, or the "zoster fever" of Landouzy. He feels that the dualist view is based rather on sentiment and theory than on precise, carefully observed facts amd serological proof. In this soldier each chicken-pox eruption was accompanied by an identical herpetic eruption, suggesting very strongly that the two eruptions depended strictly on a common ætiological factor. Dr. R. L. Thorold Grant [2] describes a case of varicella breaking out in a woman of 37 with severe bilateral herpes, and Dr. D. E. H. Cleveland [3] one of herpes in a mother, followed after the correct incubation period by varicella in her daughter, and then, after a second incubation period, the appearance of a typical varicella rash, accompanied by erythema nodosum of the legs, on the mother. Both these cases seem to support the theory of common origin. Again, Dr. von B. M. van Driel [4] had a Javanese man of 28 with a typical varicella rash following a herpes of the left upper arm, and another of 26 with a herpes following a varicella. He made the experiment of inoculating four children of varying ages, and two young men with fluid from herpetic blebs. Except for one of the young men, none of the subjects showed more than a slight erythema at the site of injection; this man fell ill 12 days afterwards with typical varicella. The children might have been expected to remain immune; some would think herpes a more likely reaction than varicella in the young man, but presumably chicken-pox is not endemic in Java.

The arguments in favour of common origin were well summarised by Dr. Flandin in the discussion on the first case. He said that, histologically, the vesicles in the two conditions are identical; biologically, there is an absolute specificity of the fixation reaction between the two; and, experimentally, the inoculation of the contents of herpes vesicles into children who have not had chicken-pox gives the same results as "varicellisation." Inoculation with herpes confers immunity to chicken-pox. Epidemiologically the incubation periods correspond. Dr. M. A. Netter and Dr. Achille Urbain have recently investigated the deviation of the complement in these cases. Out of 100 herpes subjects, of whom 84 had had no apparent contact with varicella, 93 showed deviation of the complement, whether the antigen were taken from varicellar or herpetic vesicles. Similarly the results with varicellar serum were identical with either antigen. These workers concluded that poisons like arsenic, bismuth, and mercury produce herpes by acting as "agents provocateurs" of a virus which up till then had been harboured with impunity by the patient.

At the Brussels Congress in 1926, Flandin suggested that chicken-pox might be an early manifestation—and, indeed, herpes is rare in children—while herpes was the later systematised form, appearing in a subject immu against chicken-pox. On this hypothesis an attac herpes would be a reinfection or the result of a lo immunity from some infectious or toxic cause.

THE TREATMENT OF ACUTE AND CHRO LARYNGITIS.

To the Editor of THE LANCET.

SIR,—Mr. Mollison, in his article on this subject in issue of July 21st, mentions that faulty methods of production should be corrected. May I say that this always include instruction in breathing through the in view of the fact that one of the causes of laryng inhalation of dust.

Most people are under the impression that they breathe through the nose because they do not sit with mouths open when not talking or singing. They d realise that they breathe through the mouth when voca and this means that the air is taken unwarmed, unmois and unfiltered direct into the pharynx, larynx, win and lungs. Few know that it is possible to breathe th the nose without closing the mouth; indeed, many teachers state that it is impossible. At most it is cor that though it *can* be done it involves undue pause a making of a loud sniff. But both these objection obviated if the necessary practice be carried out to the dilators of the nostrils, and the soft palate, activ flexible. Breath can then be taken quickly and silently through the nose with the mouth open.

All voice users should be taught this, and to non more important than to actors and auctioneers, who in places that are laden with dust. If they will instruction in the use of the voice, learn to breathe a through the nose, and follow the direction of their m man to sniff up their nostrils a little of the medicated lient that has been prescribed for them (and which, on in I usually find they forget to do), they will be saved siderable pharyngeal irritation as well as the more laryngitis.—I am, Sir, yours faithfully,

KATE EMIL BEHN.

The Moor House, Lane End, Bucks, July 26th, 1928.

THE COST OF MOTOR ACCIDENTS.

Sir Arthur Stanley last week opened the new out-pa department of the Wolverhampton and Staffordshire pital, which has been erected as part of a reconstru scheme to cost £45,000. He said that figures which had compiled for him showed that the extra cost of motor dents to the hospitals is £250,000 a year, of which £30,000 is recovered from insurance companies. In additi a large reception hall, the new department includes consu and examination rooms for ear, throat, and nose c two consulting rooms for physicians and two for surg with four examination rooms; rooms for the treatme fractures and orthopædic cases; a small operating the sterilising and anæsthetic rooms; a recovery room eight beds for use after minor operations; an isolation and a venereal diseases department.

Corrigendum.—In our report last week (p. 189) o International Conference on Cancer, subject, "Diagn Methods," the remarks attributed to the Chairma closing the discussion were actually made by Sir Wi Willcox.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &

WEST LONDON HOSPITAL POST-GRADUATE COLL Hammersmith, W.

TUESDAY, August 7th.—10 A.M., Medical Regis Medical Wards. 2 P.M., Mr. Addison: Operat 2 P.M., Dr. Shaw: Medical Out-patients.

WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseas Children. 2 P.M., Dr. Scott Pinchin: Medical patients. 2.30 P.M., Mr. Donald Armour: Visit.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurolo Department. 2 P.M., Mr. Donald Armour: Operat 2 P.M., Mr. MacDonald: Genito-Urinary Departm

FRIDAY.—10 A.M., Dr. Pritchard: Medical W 12 noon, Dr. Ironside: Clinical Demonstrat 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9 A.M., Mr. Vlasto: Throat, Nose and Operations. 10 A.M., Dr. Owen: Medical Diseas Children.

St. Cyres Lecture

ON

ART AND CIRCULATION IN A TROPICAL AVITAMINOSIS (BERI-BERI).

vered at the National Hospital for Diseases of the Heart, London,

PROF. K. F. WENCKEBACH, M.D., F.R.C.P.

(From the First Medical Clinic, Vienna.)

ORTY years ago, as a young doctor in my own ıtry, I was intimately acquainted with the two ch scientists, Pekelharing and Winkler, who, as a rnment committee, had studied beri-beri in the ch Indies. In those days nothing was known of etiology; my authorities believed it to be an tious disease. Eykman and Grijns had not yet overed its causation, but many of its clinical ures had been described, and it was generally wn that, to quote a British poet—

> "Beri-beri is very, very
> Hard on the nerves——,"

moreover, very "hard on the heart" also. I greatly impressed by the astonishing facts that ents seem to die of complete failure of the right t only; that the opinion (accepted as a dogma) that this heart failure must be due to a degenera- of the vagus nerve; that patients may die 24 s after having been in seemingly good health; there was an "idiopathic" hypertrophy of the le heart with evident lack of contractile strength he chief characteristic; and that vitamin B had raculous effect on a heart which refused to react ny cardiac drugs—all these facts suggested to the existence of some quite peculiar morbid ess. Some seven years ago I explained this rtant problem to a young friend, Dr. Aalsmeer, turer on internal medicine at the medical school native doctors at Surabaya (Java). He devoted od deal of time and interest to the question and autumn returned from the Dutch Indies with plete clinical records of the cardiac aspect of disease. These data, illustrated by X ray ographs and electrocardiograms, provide us a veritable "natural history" of the circulatory ratus in beri-beri cases.

SE, SYMPTOMS, AND TREATMENT OF BERI-BERI IN GENERAL.

ıe generally acknowledged ætiology lies in the nce of an accessory food factor (vitamin B), ained in the bran of rice and cereals. The se makes its appearance where polished rice is exclusive diet. Proof of this pathogenesis is shed by the results of the sole treatment—viz., ion to the diet of vitamin-containing foodstuff, as rice-bran, bran extracts, or a certain bean, n in Japan for over ten centuries (*Phaseolus atus.* Malayan: katjang idjoe). Even in very e cases it relieves the serious symptoms. The ipal pathological changes are:—

Degenerative processes in the peripheral ous system, damaging and even destroying the heral motor and sensory, as well as the sympa- c and parasympathetic elements. The symptoms hose of extensive polyneuritis.

Anasarca and serous effusion in the large ies. In chronic cases there may be a condition treme general atrophy and dryness of skin and es, the so-called "dry form."

Heart disease, characterised by general feeble- of the circulation, palpitations on the slightest ion, swelling of the liver and œdema, with al swelling of the limbs. This heart failure ry often the cause of death.

CLINICAL ASPECTS OF HEART AND CIRCULATION.

I rely on the work of Aalsmeer, correlating it with the earlier work of Vedder, Castellani, Chambers, and Manson, in English; of Scheube, Nocht, and Mense in German; of the Dutch authors Pekelharing and Winkler, Kieviet de Jonge, de Langen; and the many Japanese contributions, culminating in the important work of Shimazono, whose conceptions are in many respects identical with those of my collaborator.

The following points may now be taken as well established:—

1. From the beginning of the disease the whole heart, right and left, is enlarged; X rays show not only an enlargement to the right, but also bulging of the left auricle in the so-called "taille" (left upper border) of the heart shadow. The left ventricle, too, is clearly larger than normal. It is impossible to decide whether, in this first period, the enlargement is due to dilatation alone or to hypertrophy of the muscle wall also.

2. This enlargement and corresponding failure of the heart increases more or less rapidly, sometimes in a few hours, *but chiefly involves the right heart.* The prevalence of right heart failure and right heart widening and hypertrophy is mentioned by everyone who has studied the disease at the bedside and post mortem. A remarkable clinical manifestation is the disappearance of the apex-beat and the substitution for it of a curious wriggling, fluttering motion of the heart muscle, which the patient himself feels and which is easily seen on inspection and felt by palpating with the whole palm of the hand.

3. Increasing stasis takes place in the liver and venæ cavæ, and in acute cases this causes an enormous, painful swelling and bulging of the liver, ascites, and sometimes sudden death.

4. Even in the most serious cases there is never any irregularity of the heart, no extrasystoles, flutter, or fibrillation. The electrocardiogram never shows any disturbance of stimulus conduction. The ventricular complex is perfectly normal, and the size of the different waves rather exaggerated, the only peculiarity being a certain degree of preponderance of the right ventricle.

5. The pulmonary circulation is completely free from any sign of stasis, œdema of the lungs only showing itself in the last moments before death. There is no other disease of the lungs, no true emphysema, no arterio-sclerosis or spasm of the pulmonary arteries, which might cause right heart failure.

6. Apart from variations in the course, dependent on the relative intensity of neuritic manifestations on the one hand and of cardiac disease on the other, two forms of beri-beri are generally recognised—namely, a chronic and an acute, so-called pernicious and usually fatal form. The latter is now much less often seen than it used to be, since specific treatment has almost abolished it.

7. The whole series of heart remedies and diuretics (digitalis, strophanthin, caffeine, theobromine, thyroid, novasurol, salyrgan, &c.) is of no real use for the beri-beri heart. Vitamin B alone is an immediate and usually complete success. At autopsy the heart shows enlargement of its cavities and apparent hypertrophy of its walls, both much more pronounced in the right side of the heart. Microscopically there are no striking changes in the heart muscle-fibres and no inflammation.

DILATATION AND FAILURE OF THE RIGHT HEART.

The first unsolved problem of the beri-beri heart is the extreme widening and failure of the right heart in contrast with the relative smallness of the left ventricle and the absence of pulmonary stasis. This seems the more enigmatic, as there is proof that both sides of the heart suffer at the beginning of the disease. The soft and frequent pulse, however, the curious wriggling motion of the enlarging heart, and the progressive over-filling of the proximal parts of the venous system (v. cavæ and liver), are undeniable signs of the heart's incapacity to convey the whole quantity of affluent blood from the

venous into the arterial side of the vascular system. Clinical experience has taught me *that in such cases of increasing insufficiency of the whole heart the right heart is doomed beforehand to suffer much more than the left, and even to suffer to the profit of the latter.* If the strength of systole is decreasing in both ventricles equally, the moment will come at which both ventricles will fail to discharge their contents completely. A larger amount of residual blood than normal is retained in the heart. This larger post-systolic ventricular blood volume, together with a normal onflow of blood during the diastole, must necessarily result in a greater filling of the heart at the beginning of the next systole. This increased load will soon become too much for a heart already unable to discharge a normal quantity of blood. The output will become smaller and smaller, the filling of the arteries will be less, and the diastolic filling of the heart and the venous stasis before the entrance port of the heart must both increase. This being so, two factors will establish a marked difference between the right and left heart.

The first of these is the anatomical inequality of the two ventricles, the right being of lighter build, and provided with a thinner wall. The tricuspid valves are implanted on a much weaker ground than the mitral; there is no strong fibrous ring supporting them, they are condemned to share the distension of the right ventricle, and consequently are more liable to incompetence. Once this incompetence is established, blood passes from the right heart backwards into the veins and liver and the arterial output of the right ventricle is greatly reduced.

A still more important factor is at work. In the blood stream, moving "quasi in circulo," the right heart is located higher up the river than the left. As a consequence, the right heart has to deal under all circumstances with the whole volume of blood returning from the periphery to the heart, *the left heart not receiving more blood than the right heart is able to transmit.* Consequently the right heart is all the time struggling for life against an ever-increasing overfilling and widening, but the left heart is spared a similar burden. *The more the right heart suffers and fails, the safer the left heart becomes*, working under easy conditions and decreasingly threatened by such factors as might lead to overfilling and dilatation.

In such circulatory disturbances, despite a smaller output of the left heart, this smaller minute volume will reach the great veins and the right heart in due time. This holds good even in severe degrees of mitral stenosis, in which an extremely high arterial blood pressure may be maintained. Even after the final standstill of the heart in the first moments of death this function of the arterial wall (perhaps the last of life) is maintained, so that post mortem the arteries are found empty and the venous system filled. Therefore a smaller supply of blood to the aortic system cannot be expected to relieve the difficulties of the right heart in the same way as a smaller supply to the pulmonary arteries relieves the left heart.

These explanations make it possible to understand the cardiac and circulatory phenomena of beri-beri, the initial widening of the whole heart, the ever-increasing bulk of the right heart, the ever-decreasing cardiac systolic output, and the progressive engorgement of the proximal venous system, venæ cavæ, and liver. It is now easy to see how in acute attacks of beri-beri a sudden failure of the right ventricle with tricuspid incompetence puts the great veins and the liver under systolic ventricular pressure. These are distended to the highest degree and sudden death ends a condition of extreme suffering, the horror of which was so dramatically described by Manson in his handbook of tropical diseases. Throughout this unsuccessful struggle of the right heart the lung fields on the X ray plate are quite clear; there is no lung stasis, no râles, and no pulmonary œdema, and the left heart is not greatly enlarged but, on the contrary, is smaller and poorly filled. A small and rapid, but fairly palpable, pulse gives proof of the relative competence of the left ventricle, until at the last moment before death the latter loses its systolic power, succumbs, and leaves the lungs with stagna blood and signs of ante-mortem œdema.

This simple mechanism, which explains the w circulatory complex of beri-beri and the post-mo findings, has great importance for general c ology. The so-called safety-valve action of tricuspid valve, hepatic stasis relieving the from threatening high tide, is familiar to a number of us, but well-defined conditions functional heart disease, involving both sides of heart equally, are rather rare. They may be fo in the course of acute infectious diseases (pneumo diphtheria, and others), but here so many diffe toxic and reflex influences complicate the pic that the separate influence of each is not e discriminated. Another condition in which sides of the heart are hampered in their actio exactly the same extent is rapid paroxysmal ta cardia and auricular flutter and fibrillation. otherwise normal hearts it has been possible to s that here also there is marked stasis in the l veins and liver coincident with absence of stasis, râles, and dyspnœa. Since James Macke discovered the change of circulation caused by onset of what he called auricular paralysis, known as fibrillation, in long-standing mitral sten we have been acquainted with sudden, pai swelling of the liver; from personal experience change is often accompanied by a striking impr ment in respiration, and relief of the suffoca dyspnœa.

Once I recognised this mechanism, I was abl find it in a great many cases of slowly progres general myocardial weakness. Careful treatm with well-apportioned doses of digitalis and diure may cause lung œdema and swelling of the live disappear, even in extreme conditions, but only a time. These intervals, during which equilibr between the right and left heart is maintained difficulty, become shorter and shorter, until at treatment fails and the patient dies in a few ho In many of these cases of recurrent heart failure first and chief symptom is a rapid and very pai swelling of the liver. Even in rapidly fatal c the same symptoms may be found, râles and œdema only showing themselves during the hours of life.

In all these conditions the curious relation between right and left heart failure may be recogni but nowhere is it so uncomplicated, so regular, so easily demonstrable as in the beri-beri heart. T there is a law of circulatory correlation between two sides of the heart which may be formulate follows: *In equal and increasing feebleness of whole heart muscle the patient suffers most and from the failure of the right side of the heart only.*

Shimazono and Aalsmeer do not accept the ventional view that degeneration of the vagus fi is the cause of the heart failure. Consider dilatation of the heart may be present long be the first manifestations of polyneuritis. Ther no parallelism between the degree of degenera of nerve-fibres and that of the heart affection; ind it is the strong, apparently still healthy pat who seems to be most liable to the serious suc acute attacks, in contrast with the patient whose symptoms are those of palsy from polyneu Aalsmeer is probably right in thinking that relatively good nerve-fibres of the strong man en him to undertake an amount of exercise which too much of his already weakened heart and ind the sudden attack of heart failure.

This vagal factor being unacceptable, we h to seek other clinical facts that would reveal the potent unknown factor of this disease. The hint is given by reasoning that, in our explana of the development of myocardial failure in beri-b there seems to be no place for the hypertrophy of heart muscle so often described. Why should muscle that from the very beginning is showing the signs of reduced contractile force and lesse output become hypertrophic? Such conceptions

pertrophie passive par faiblesse du myocarde," the individual fibres becoming weaker . . . an mpt is therefore made to compensate by increasing number of fibres—i.e., hypertrophy," do not idate the problem. The only way out of the culty seemed to be to look for another explanation he post-mortem findings of increased weight of whole heart and increased thickness of the muscle s.

alsmeer found that, even in the worst conditions ilure, the beri-beri heart gives a perfectly normal rocardiogram, without arrhythmia, extrasystoles, rotopic rhythms or disturbance of conductivity in bundle or in the conducting fibres of the ventricle. ; fact reminded me that the old observations lacWilliam record non-contracting heart muscle iout disturbance of conductivity. Thirty years Engelmann found that the frog's heart muscle n immersed for a short time in water loses its ractility but retains its excitability and its power imulus conduction, showing that this phenomenon, overed by Biedermann in voluntary muscle, s good also for heart muscle. Later de Boer onstrated that the swelling of the heart muscle, ed by the water, reduces mechanically the con- tile power of the muscle-fibre, but at the same the electrocardiogram may continue completely anged. Skramlik, Lusanna, Zondek, and Kraus onstrated the same phenomenon for other forms of r retention in muscle-fibres, and even found that size of the waves of the electrocardiogram may nlarged and the rate of conduction increased. presence in beri-beri also of this strange contrast een evident weakening of the heart muscle and undisturbed or accelerated automatic excitatory esses suggests that here also *the nature of the tion might be water retention* ("Quellung") *with quent swelling of the heart muscle-fibres*, and that swelling, rather than a true hypertrophy, may be cause of the increased weight and thickness of heart muscle wall as found post mortem.

The Water Retention Hypothesis.

ny arguments support this hypothesis. A few hs ago Tiemann showed that striated, in contrast smooth muscle-fibres, swell in water and in all rtonic solutions. The gain in weight and the ing, due to the quantity of water taken up, is in heart muscle than in common voluntary le. If the same process is at work in beri-beri ould expect to find the skeletal muscles swollen he same time as the heart. This swelling is, ct, typical of the disease, especially at the ning, long before general tissue œdema or of nerve degeneration appear. Swelling is most icuous in the muscles of the calf, which are very ul in walking and on being pinched. Pekelharing, ler, and Nocht compared the condition with "pseudo-hypertrophic stage" in progressive ular atrophy of childhood.

this hypothesis we should expect that no nent can succeed which does not free the heart e from its surplus water and drain the muscle- When vitamin B is given, the heart rapidly ishes in size and recovers its power of con- on, and the skeletal muscles share in this ss. The hard, thickened, and painful muscles e calf melt away, as snow in the sun, to es of normal size and function. De Langen, s new monograph on beri-beri, mentions this disappearance of the swelling and equally cure of the motor paralysis, less than 24 hours aking vitamin B-containing food. This remark- improvement is accompanied by a marked se in the secretion of urine. Scheube states that ng idjoe had the reputation in Japan a thousand ago of being a good diuretic. Of recent years iuretic action of rice-bran and katjang idjoe en specially investigated by Japanese scientists.[1] the extensive work on the regulation of water nge by Magnus and by the Vienna Pharmacological Institute (E. P. Pick, Molitor Baer) we learn that striated muscle may take up and, under certain circumstances, can retain large quantities of water injected into the blood or taken by the mouth. Our muscular system may be regarded as one of the biggest water reservoirs, and its contents do not appear on the balance of intake and output.

Recent research work by Tsunoda and Kura[2] gives important information concerning the anatomy and treatment of beri-beri. In pigeons exclusively fed on polished rice the sensory nerves and their endings in the skin show curious primary regressive metamorphosis accompanied by swelling and other changes in their microscopical appearance. After the injection of small doses of vitamin B all these changes and their clinical consequences disappear rapidly. The endings of the sensory and motor nerves improve rapidly within five hours after the injection. Twenty-four hours later the histological appearance is practically normal.

The conception of water-retention in the heart muscle-fibre explains all the symptoms and peculiarities of the beri-beri heart, which thus constitutes a hitherto unrecognised and unique form of heart muscle disease. Before trying to bring this curious pathogenesis into relation with other well-known facts of physiology and general pathology, I must mention an equally unique phenomenon in the symptomatology. Not only is the electrocardiogram normal during the whole course of the disease, but the rate of conduction is increased and the atrio-ventricular interval is shortened. Moreover, conduction quickens as the heart failure progresses. In the most serious and acute cases the shortest atrio-ventricular intervals were found when the patient seemed to be in imminent danger of death. With recovery the conduction slowed down to normal, even with slowing of the rate of the heart beat. The fact that the same phenomenon was found experimentally in water-swelling of the heart muscle is a strong argument in favour of the identity of this condition with beri-beri heart.

Theoretical Considerations.

It seems very probable that water-retention may be the primary cause of other manifestations of beri-beri and, in the first place, of the important degenerative processes in the whole peripheral nervous system. We have already seen that the swelling of nerve-endings in chicken beri-beri disappears completely a few hours after vitamin treatment. The microscopical anatomy of nerve-fibres and ganglion cells in beri-beri accords well with this conception, and it should not be forgotten that although motor and sensory paralysis may be found, as in polyneuritis, the primary affection of the nerve element in beri-beri is not inflammation. It is the general opinion that the anasarca is not so much secondary to heart failure, as essentially an imbibition process of the tissues. Other organs may show temporary swelling at the same time. Some of the glands seem to possess a special predisposition for this kind of water-retention in beri-beri, just as striated muscle is the first tissue to swell while smooth muscle escapes. A familiar pathological finding in this disease is swelling of the mucous lining of the gall-bladder. Kieviet de Jonge mentions a curious broadness of the face, recalling parotitis, and he found that there is enlargement of both parotid glands, the nature of which, he says, is "not œdema." Stepp thinks it probable that some of the glands, especially those secreting saliva, ceased to function.

It would be astonishing if beri-beri were the only disease in which water-retention directly damaged the heart. When an ailing heart does not react to heart drugs we generally suspect a desperate anatomical and functional condition of the myocardium; it seems possible that the cause found in beri-beri plays a part in the development of such events and might be removed by analogous forms of treatment. The first disease to remember in this connexion

[1] Japan Jour. of the Med. Sciences, 1927, viii.

[2] Virchow's Archiv, 1928, p. 267.

is myxœdema, where there is water-retention as a consequence of insufficient thyroid secretion ("Quellung"), and where water is expelled ("Entquellung") by thyroid treatment. A case of atypical myxœdema may be shortly related here:—

Some 20 years ago a small Frisian community sent a poor man to the medical clinic in Groningen because he was more or less stupid and so easily tired that he was incapable of any bodily work. His face showed a certain degree of imbecility or apathy, and his muscular function was greatly diminished; but his build was Herculean. There was no trace of œdema, the face was not swollen, and the heart seemed normal. The muscles were not only big, but very hard and of abnormal consistence; I thought this might be myxœdema of uncommon localisation. A few thyroid tablets had a most astonishing effect; the firm voluminous muscles that were very painful on pinching became thinner, softer, and fit for use again. On palpation the peculiar sensation of rolling muscle bundles returned, leaving only a few hard nodes, which disappeared in a day or two. In a week's time the normal intellect of the man had returned and he was sent back to his village and advised to take small doses of thyroid indefinitely. To the great satisfaction of his community he proved completely cured and able to do regular work, but with less Herculean muscles.

The absence of heart and nerve lesions, on the one hand, and the inactivity of thyroid in beri-beri on the other, prove that this case was not beri-beri, and the two conditions of different nature.

Another important difference was noted by Aalsmeer. In both diseases there is a greatly increased skin-resistance in the patient to the electrocardiogram; more in beri-beri than in myxœdema. But the deflections of the string are very small in myxœdema and at the least normal, or sometimes much larger than normal, in beri-beri.

These clinical facts point to the quite peculiar and specific nature of the swelling of the striated and heart muscle, which is certainly not a condition of œdema.

Heart Hormones and Automatins.

Our subject forms a bridge between scientific research at the bedside and modern experimental work on heart "hormones" (Haberlandt) and "automatins" (Zwaardemaker). Rigler[3] found that vitamin B, isolated as a pure chemical substance by Jansen and Donath, belongs to this group of substances. He believed it to be identical with histamin. The fact that the organism itself produces substances which are able to bring an experimentally stopped heart and its automatic functions back to life has already induced experimental workers to recommend these substances for the treatment of heart patients. The beri-beri heart shows that at least in some rare conditions the revival of a seemingly lost heart is possible. There are doubtless a great number of different conditions causing standstill of the heart, and doubtless we shall hear, in the course of time, of a great number of different substances which may help. The beri-beri heart shows that not every heart that stops its systolic action has lost its regular automatic vital function. The automatism may go on undisturbed, but is prevented from manifesting itself by lack of conductivity or, as in beri-beri, by interference with contractility. In such cases the active substance which restores the regular function should not be called an automatin; what happens in the heart is not revival from death, but release from bondage.

Summary.

My subject shows eloquently that careful study of the sick and their symptoms, and free experimental research are equally indispensable to the advancement of medicine.

It teaches us the existence of a law of circulatory correlation between the left and the right heart, working along simple mechanical lines of considerable clinical importance.

It leads us towards the better understanding of a disease, of which the successful treatment had already been found by experience at the bedside.

It brings us into close contact with the most modern biological problems of water exchange, of hormones, of sudden death, and revival of functions.

It seems permissible to formulate the hypot that the fundamental process in beri-beri is w retention and the consequent swelling of ce vital tissues, especially nerve and striated musc

THE LATER RESULTS OF PARTI GASTRECTOMY.*

By NORMAN C. LAKE, M.D., M.S., D.Sc. L F.R.C.S. Eng.,

SURGEON TO CHARING CROSS AND BOLINGBROKE HOSPI ASSOCIATE EXAMINER IN SURGERY, UNIVERSITY OF LON

Few subjects have received more attention or been the cause of intenser controversy during r years than that of the nature and treatment of g and duodenal ulceration. From the surgical poi view the discussions have, for the most part, r around the relative merits of partial gastrectom gastro-enterostomy. It is not proposed in article to consider partial gastrectomy as a treat for new growths—for here the obligations o surgeon are sufficiently clear—but to limit the r to cases of apparently non-malignant ulceration.

It will be well at the outset to summaris standpoints taken by the several schools of thou the present day. (1) The first school believe operative treatment should never be adopted i absence of acute complications such as perfora they maintain that the symptoms can be adeq controlled by purely medical measures. For ob reasons this group consists almost exclusive physicians. (2) The second group comprises who think that operation may be occasionally ju in very persistent cases, and especially in the pr of such complications as pyloric stenosis. Int group fall many physicians and a few surgeon have been unfavourably impressed by the recu of symptoms or the onset of jejunal ulceration gastro-enterostomy. (3) The majority of E surgeons belong to the third group and favour g enterostomy for chronic cases, after medical trea has been given a trial, but would treat all acute medically. (4) Others advocate gastro-enteros with or without pyloric exclusion, for practica cases. (5) Yet another school consider that f majority of cases of gastric ulceration partial ga tomy is indicated, but perform gastro-enterosto duodenal disease. (6) The last school believe gastrectomy to be the operation of choice in all and would always perform it for both gastri duodenal ulceration if the technical difficulties a insuperable.

With such diversity of opinion the only safe is a critical and, as far as possible, unbiased exa tion of the results. Since this article will dea with the surgical aspect it is essential, as a pro to give reasons why the claims of the first schoo surgical treatment is unnecessary, cannot be tained. Unfortunately, perhaps, for the sur proper judgment, the great majority of the upon which he operates have already recei prolonged course of medical treatment, a circum likely to prejudice his opinion of these claims. discovery of signs of old healed ulcers is offset presence of the fresh outbreak for which the ope is undertaken. The treatment therefore, even i cases, has done little more than allow the o ulcer to heal without removing the cause. mortem evidence of completely healed ulcers is, experience, much rarer than that found at ope for a fresh outbreak; it thus appears reasona conclude that medical treatment can rarely about permanent cure. Moreover, relief of sym is not necessarily accompanied by cure of the

Data.

he cases reviewed occurred in the author's practice ng the five years 1922–27, and none of less than year's post-operative history are included. The l number of gastric operations was 221, and of e 65 were partial gastrectomies and 71 gastro-rostomies; the percentage of gastrectomies, ever, rose from 5 per cent. in the first year to er cent. in the final year under review. In the instance inquiry was made by a circular letter ding a series of simple questions designed to come any reluctance on the part of the patient to rd unsatisfactory results; for previous experience shown that patients hesitate to state slight nveniences.

s many patients as possible were then personally viewed and re-examined; plenty of volunteers found for additional investigation by bismuth , test meal, blood counts, bacteriological tests, &c. his way the subsequent history of a considerable ber has been obtained in detail, with records of ltimate results of the special tests. In classifying results, those who, in addition to giving entirely factory answers to the questions, added enthusi-comments about their health, were called isfactory++." Those who answered all ques-s in a gratifying manner without comment were ed as "satisfactory+." Where the patient had ved complete relief of symptoms but complained tly of occasional fullness and constipation the t was called "satisfactory." Patients who stated were better but still had attacks were "unsatis-ory," while patients with recrudescence of ptoms or development of fresh ones were "unsatis-ory+." One of the questions related to the type od taken, and unless the reply was that all foods taken without restriction the patient was not ed in the "satisfactory" group. Of the 65 gastrec-es 8 were subsequently proved by section to arcinomatous ulcers, and have therefore been d in a separate table.

.. 12			

us 95 per cent. of the partial gastrectomies have ymptoms of any sort and are able to take all of food without restriction, and 51 per cent. he gastro-enterostomies come into the same ory. Only 2·5 per cent. of the gastrectomies nsatisfactory, but 36 per cent. of the gastro-ostomies fall under this heading. There can o doubt, therefore, that from the point of view omplete and permanent relief of symptoms ectomy is a much more satisfactory operation gastro-enterostomy, although 63 per cent. of patients treated by the latter method are cured or improved.

The mortality figures rather counterbalance this satisfactory conclusion, for 6 of the gastrectomy cases died within four weeks of the operation, 2 of hæmorrhage, 2 of pneumonia, and 2 as the result of gastric fistula following the Billroth 1 type of anastomosis. Both these last two were debilitated patients with enormous ulcers (one malignant) very adherent to surrounding structures, and no other procedure seemed possible. The Billroth 1 operation is notoriously liable to leakage if there is the slightest tension on the anastomosis, which is difficult to avoid after an extensive resection. It is legitimate, therefore, to exclude these from the ordinary mortality. They come early in the series, and with additional experience it is certain that they would now either be left alone or treated by jejunostomy. The other four cases constitute a mortality of 6·3 per cent., a figure capable of reduction, probably to half, with care. On the other hand, there was no mortality in the gastro-enterostomy series. Further analysis of the mortality figures gives the following:—

	Per cent.		Per cent.
Gastro-enterostomy	0	Billroth 2..	7·5
Sleeve resection	20	Billroth 1..	100
Polya	0		

The 20 per cent. for sleeve resection is obviously misleading, as there were only five cases in the series and the death of one from hæmorrhage was due to the use of catgut subsequently found to be defective. According to these results the Polya would appear to be the safest type of gastrectomy, but the total number of each type performed must be taken into consideration.

Gastro-enterostomy without perforation	61	Polya	18
		Billroth 2	40
Sleeve	5	Billroth 1..	2

Even then the Billroth 2 operation is found to have the greater risk, but there was no mortality when it was performed in two stages. The further statistics of the gastrectomy cases are as follows:—

Male 46 .. Average age, 39		Incidence of	13 per cent.
Females, 17 .. „ 44		carcinoma cases	12 „

The types and position of ulcers were: gastric (body) 12, gastric (pyloric) 5, duodenal 6, doubtful (pyloric) and not mentioned 21, multiple 6, jejunal 7, carcinomatous 8. This list only records the position of the chief ulcer and does not take any account of healed scars or other small ulcers. Had these been included the percentage of multiple ulcers would have been about 90.

After-results of Gastrectomy.

All the gastrectomy cases have gained weight since the operation, some of them as much as 3 st., and they all look remarkably healthy. In one or two cases there appears to have been an excessive deposition of fat, and two mentioned the development of an abnormal desire for highly spiced foods.

Practically all the cases had fractional test-meals carried out shortly after operation, and with one exception showed complete achlorhydria. Those taken after an interval of several years demonstrate quite conclusively that the achlorhydria is permanent. None of them showed the slightest trace of free hydrochloric acid. The average total acid was less than 10, and the average total chlorides in the absence of bile 29; when bile was present this rose to over 70. Typical examples are given in Figs. 1 and 4. Bismuth meals, also conducted after a long interval, show that the remnant of stomach undergoes considerable increase in size; emptying is rapid, never taking longer than an hour and usually much less. The stoma in the Polya and Billroth 2 operations lies more or less horizontally, and is fairly well defined in the radiograms. There is no radiographic evidence of any effect upon the movements of the small or large intestines.

Blood examination revealed a high count corresponding to the patient's appearance of health; no

case showed less than 4,800,000 red cells. The average of all the counts gives—

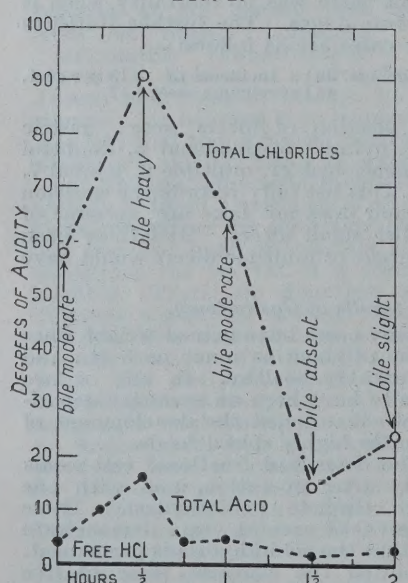
Red blood cells	5,250,000	Eosinophils	1·5 p.c.
Hæmoglobin	91·2 p.c.	Basophils	0·5 ,,
Colour-index	0·84	Large hyalines	5·4 ,,
White blood cells	7,160	Lymphocytes	30·4 ,,
Polymorphs	61·8 p.c.		

Bacteriological examination of the teeth, gums, tonsils, and throat in a series of cases yielded streptococci in several, but in no case were they hæmolytic.

The reasonable deductions from these statistics are that gastrectomy gives much more satisfactory ultimate results than gastro-enterostomy; that it has a mortality of about 7 per cent., whereas there is no mortality from gastro-enterostomy; that jejunal ulceration does not occur after gastrectomy, whereas a proportion of the gastro-enterostomies have symptoms suggestive of such ulceration, and subsequent gastrectomy has sometimes been necessary for definite jejunal ulceration. The exact incidence of jejunal ulceration in the gastro-enterostomies is uncertain because some cases with suggestive symptoms have not been explored, but if we include these the percentage is over 10. The gastrectomies include a large percentage of the more difficult and serious cases with extensive ulcers penetrating surrounding structures, while the gastro-enterostomies include most of the cases of simple duodenal ulceration where the operation was easy.

The total number of jejunal ulcers is too small to allow any definite conclusions, but the accepted idea, that they occur more frequently after duodenal ulceration, is supported, while excision of the original ulcer at the time of operation appears to make no difference to their incidence. Some competent observers deny that jejunal ulceration is rare after gastrectomy, and also state that its incidence is as high after gastro-enterostomy in those cases that show no post-operative acid as in those where acid remains high. There are objections to both these arguments against the importance of hydrochloric acid in the ætiology of jejunal ulceration. It has been definitely established that some patients were not achlorhydric after gastrectomy owing to the very limited resection performed, often little more than a pylorectomy. In the author's experience those cases of gastro-enterostomy which show little or no acid after operation will be found to have had very little acid to start with; this usually means that the ulceration is almost always multiple and of long duration, with the development of a secondary atrophic gastritis (Fig. 2). Under these circumstances the anastomosis may actually be made at the site of mucous ulceration, a condition which would naturally predispose to the development of jejunal ulcer. It will also be obvious that unless the total chlorides are estimated it is impossible to state whether the achlorhydria is due to neutralisation or lack of secreti In the former case there is no guarantee that test-meal is an accurate indication of the acid cont (or its absence) after ordinary diet.

FIG. 1.



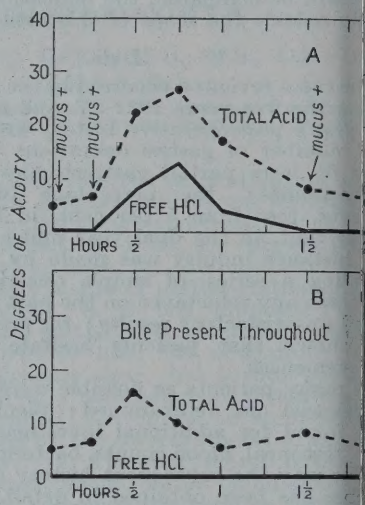
Test-meal after partial gastrectomy. The effect of the presence of bile upon the total chlorides is well seen.

If it be agreed that the results of partial gastrecto are much better than those of gastro-enterostomy, following questions arise: 1. Is the mortality of par gastrectomy justifiable? 2. Are the results p manent? 3. Are there any remote effects of the removal of large portions of the stomach? 4. In what way does gastrectomy act?

The Alleged Deleterious Results of Gastrectomy.

In the series under review the oldest cases have more than six years' post-operative history, while quite a large proportion have more than three years. It may be doubted whether even these periods constitute a true test of permanency, especially since many cases of jejunal ulceration after gastro-enterostomy do not become urgent many years (certainly more than ten). Neverthel most patients complain of premonitory sympto within a limited time (usually a few months) of operation, whereas the gastrectomy cases all expr themselves as entirely free of any warning sympto Their general state of health, too, is patently inco patible with continued ulceration. It may be accept therefore, as the result of actual experience, that good results obtained are permanent in the practi application of that term.

FIG. 2.



Curves obtained before operation (A), after operation (B), in a case of prolon multiple gastric ulceration with atro gastritis, showing the small acid cont before operation (gastro-enterostomy v cauterisation of the ulcer). The ach hydria is chiefly due to neutralisat which would probably not be so comp after an ordinary meal.

It has often been suggested that untoward rem effects may follow partial gastrectomy, especially all the cases have complete achlorhydria. T relationship of achlorhydria to pernicious and ot anæmias has been thought by some to be one of ca and effect; for this reason the blood examinati made some considerable time after the gastrecto are particularly interesting. No case shows any s of primary anæmia, but the hæmoglobin and colo index are rather below normal; the total leucoc count is normal, the polymorphonuclears be perhaps slightly low. It can therefore be stated w confidence that this series affords no evidence of a deleterious effect of achlorhydria upon the blo count. (Cases of malignant ulceration must obviou be excluded; some of the discrepant results obtain in the past may possibly be explained by failure separate malignant and simple cases.) No patient known to have died since the operation, so that a subtle intangible lowering of the resistance to ot diseases, especially infections, can be excluded. T stools were not examined bacteriologically, but th were no clinical signs of any abnormal infectivity the intestinal contents, nor was there any radiograp evidence of nervous or chemical interference with t action of the small or large intestine.

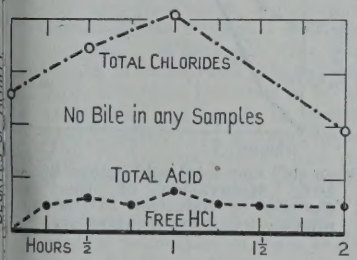
The tendency to excessive deposition of fat in t cases could conceivably be due to some alteration the metabolism of food, but is probably more correc

plained as an inability of the tissues, often long rved, to deal efficiently with the sudden excess of d products with which the patient, now relieved of pains, supplies them. In other cases it may be rely the resumption of the patient's normal build l habit. The slight qualitative change in appetite orted by two patients may be due to the removal of arge sensory area from the stomach mucosa, but s too vague and trivial to warrant much attention. On the whole, then, it seems that there is not an a of evidence that any remote deleterious effects ow gastrectomy. Indeed, the patients appear to in a much better general state of health than they l been for many years.

The Mortality of Gastrectomy.

The definite, if small, mortality associated with trectomy cannot be dismissed so easily. In this es the gastrectomies include all the most difficult es, while the mortality associated with any sequent operation for jejunal ulceration (notorily difficult to treat and usually demanding partial trectomy under the worst circumstances) should remembered in estimating that of gastro-enterosy. With these modifications the difference in the rtalities is much reduced, some say equalised. All ussions of mortality are, however, futile until type of case for which the operation is to be ted is defined. Those who recommend gastrectomy all cases of duodenal and gastric ulceration agree t the mortality is little greater than that of gastroerostomy with its later complications; those who t the operation to large gastric ulcers state ectly that such conditions are very serious at the t and that, provided the mortality is small, the ration is amply justified. The mortality is able of further reduction; probably the surgeon's experience is the most important factor, but greater pre- and post-operative care are possible. Transfusion, special dieting, attention to oral sepsis, and especially the postponement of operation upon any signs of infection of throat or lungs should never be neglected. In erious cases the operation should be a Billroth 2, ormed in two stages with a suitable interval.

FIG. 3.

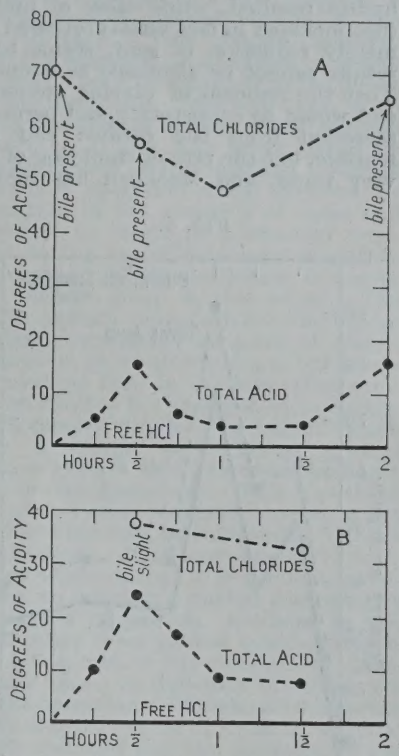


-meal after partial gastrectomy, owing achlorhydria and low total lorides in the absence of bile, indicating at achlorhydria is not merely a estion of neutralisation.

fter the operation every precaution must be n to prevent chest complications. The value of nsive splanchnic and field block anæsthesia is otful; it was used in a large percentage of these s without any effect upon the incidence of chest plications, though it probably rendered the alescence smoother. In most cases the general sthetic was intratracheal ether or chloroform, and e was no noticeable difference in the effects upon lungs. There is no doubt that post-operative eumonia" in these cases is due much more to the ring of vitality and interference with upper minal movement than to the type of anæsthetic, hat speed, facility of access, and clean, gentle ipulation are of great importance. The other es of mortality are definitely avoidable by ation to technique, and there is no reason why it ld rise above 2 or 3 per cent. If such a figure be oached there can be no doubt that the operation t only justifiable but actually advisable instead of o-enterostomy.

mong other arguments in favour of gastrectomy is avoidance of the risk of subsequent malignant change in the ulcer. Some cases not included in this series definitely prove that such a change can occur, even after gastro-enterostomy, but it is certainly uncommon, and the high percentages given by some observers are undoubtedly founded upon a misinterpretation of the premises necessary to establish a diagnosis of malignancy. If malignant change were common, any series of gastro-enterostomies should show a fairly large subsequent mortality from this cause; even if it be assumed that gastro-enterostomy largely prevents malignant changes, a percentage of the cases will be unknowingly malignant when operated upon. The cases of carcinoma included in this series were for the most part only definitely diagnosed microscopically after removal. The conclusions are: (1) that malignant change can occur in ulcer, although it is probable that the majority of carcinomata start de novo; (2) that a certain number of cases, apparently of ulcer, will be found definitely malignant upon microscopy. These are obviously arguments in favour of gastrectomy, but neither event is common, and I would not stress them.

FIG. 4.



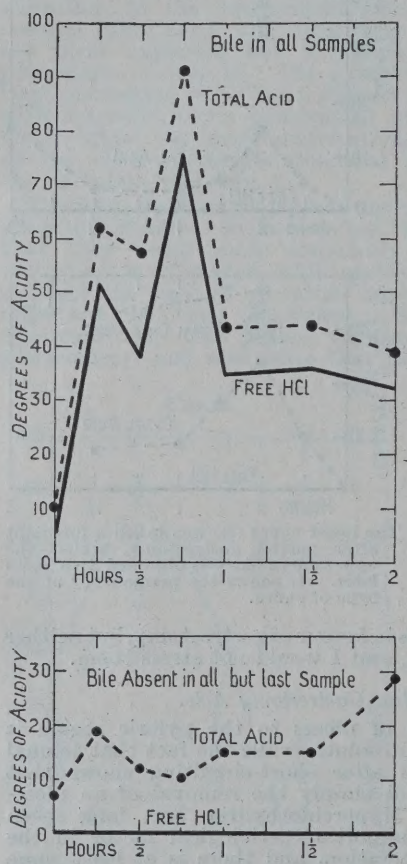
The lower curve (B) was taken a fortnight after partial gastrectomy, whilst the upper curve (A) was obtained two years later. It shows the permanency of the type of curve.

How Gastrectomy Acts.

The limitation of ulcers to the pyloric region is marked, but not absolute, while the fact that jejunal ulceration occurs after short-circuiting shows that gastrectomy is not simply the removal of an ulcer-bearing area. Hyperchlorhydria has long been accepted as an important ætiological factor in the production of ulceration, and there is at least some association between the two. Accordingly it is assumed that gastro-enterostomy produces its effects by neutralising the acid with the alkaline contents of the jejunum. The post-operative test-meal curves show positively that there is an essential difference between the effects of partial gastrectomy and gastro-enterostomy. The gastro-enterostomies show merely a reduction in acidity (Fig. 5), while the gastrectomies reveal complete absence of free hydrochloric acid. This is not simply due to more effective neutralisation, for the total chloride is always very low in the absence of obvious bile or mucus (Fig. 3). This raises a point of some importance in the physiology of the stomach, for it can only be explained by assuming: (1) that the pyloric half of the stomach is the only portion capable of secreting acid—this is at variance with ordinary physiological teaching; (2) that the operation so profoundly modifies the general activities of the stomach, either by nervous reflex or locally, that the remaining cardiac half permanently ceases to secrete acid. Recent work upon the control of

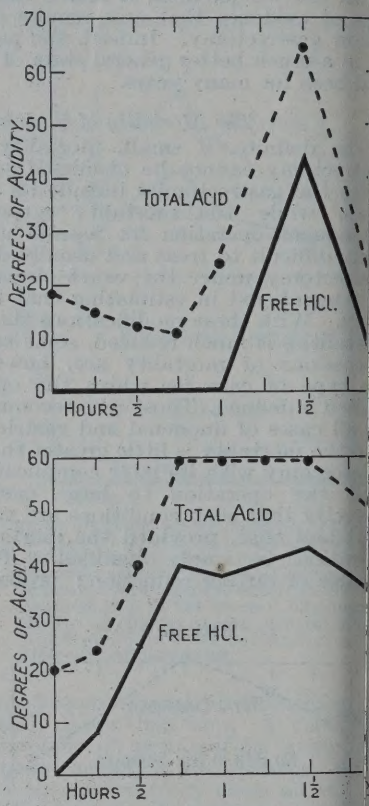
secretion, the secretion of neutral chlorides, and the effect of duodenal regurgitation has amply shown that the whole question is much more complicated than was formerly believed; I hesitate, therefore, to draw dogmatic conclusions upon what may easily prove to be inadequate data. Whatever the laboratory findings, however, these clinical facts demand recognition and critical examination. The fact that where the whole of the pyloric half was removed, no matter how much of the cardiac portion remained, complete achlorhydria resulted, while cases of limited pylorectomy (not included in this series) revealed in every instance merely reduction of acid, seems to prove that the results cannot be dismissed as erroneous or fortuitous. That the removal of varying amounts of the pyloric end would so consistently and permanently affect the secretion from the cardiac end scarcely appears feasible, but the rate of emptying of such a stomach is very rapid, and MacLean has recently shown that "the gradual decrease in acid concentration in the stomach during the completion of ordinary digestion in normal dogs is a function of the stomach itself, and in no way dependent upon regurgitation of alkaline duodenal contents." It may be that the absence of secretion is also an intrinsic "function" of the stomach when its general physiology is disturbed by the performance of a gastrectomy. A nervous reflex effect is excluded by the fact that sleeve resection, in which the division of nerves is almost as extensive as in the usual partial gastrectomy, is not followed by achlorhydria. The same applies in greater degree to definite denervation operations of which a typical post-operative curve is given (Fig. 6). The simpler suggestion—i.e., that the acid-secreting portion is removed—is probably the correct one. The physiological teaching with which this disagrees is chiefly founded upon experimental work on dogs, the results of which should only be applied with great reservation to human beings. The histological evidence of the presence of acidophile cells in the cardiac glands is also inconclusive, for it may be argued that the cytoplasm of a cell secreting acid would be left on the alkali side of neutrality. The intimate physiology of the cells is not sufficiently understood for us to dedu the exact chemical changes which occur in t cytoplasm. A test-meal after partial gastrectomy not without difficulties and uncertainties, and t results may be due to the collection of material fro the jejunum rather than the remaining stomach. T characteristic curves given here, especially the effect of bile upon the total chlorides, and the general uniformity of results over a series of cases, suggest, however, that they are not the result of technical errors.

FIG. 5.



The upper curve was obtained 16 years after performance of posterior gastro-enterostomy, and shows that despite admixture of bile the free acid still remains high. At operation the pyloric ulcer was found to penetrate surrounding structures: the whole pyloric end of the stomach, including the anastomosis, was excised, and a fresh Polya type of anastomosis was performed to the cardiac end. The lower curve shows the resultant achlorhydria, occurring despite absence of bile. These curves demonstrate the profound difference between the effects of gastro-enterostomy and gastrectomy.

FIG. 6.



Free HCl and total acid curves before after denervation of the stoma showing no reduction in free acid alteration in general character.

Those who believe that hydrochloric acid bears an ætiological relationship to ulceration find in this result a ready explanation of the success of partial gastrectomy. The growing school, however, who regard acid and ulcer as concurrent effects of an unknown cause will still be at a loss. On the whole, the evidence derived from these cases of gastrectomy is rather in favour of reinstating acid as an important ætiological factor which may, of course, and indeed probably is, itself secondary; for not o is the abolition of acid the most conspicuous res of the operation, but the rarity of subsequent jeju ulceration is also best accounted for in this w (Some believe that this result is due to the remo with the original ulcer of the possibility of infect of the suture line. As we have already se however, excision of the ulcer with gastro-enteroste is not followed by immunity.)

The activity of pepsin is commonly ignored considering the ætiology of ulceration, largely account of the difficulties of quantitative estimatio enzymes, but it would probably be more accurate use the term "pepsin hydrochloric acid" in place plain "hydrochloric acid" throughout. The idea t the pyloric end of the stomach is responsible in n for the production of acid deserves the attentio physiologists. It certainly fits in satisfactorily w the division of the stomach into two function separate portions, a view supported to some extent morphology and by radiology, the cardiac end be considered merely as a storehouse for food ta intermittently at meals, from which the activ digestive pyloric end is slowly and continuo supplied with pabulum.

Predisposing Conditions for Ulceration.

There has, in the past, undoubtedly been too g a tendency to think of gastric and duodenal ulcera

a local isolated lesion, a tendency which is reflected the embolic theory and others where the microscopic atomy of arterial distribution is held responsible. reful examination of the ulcerated stomach or odenum shows the great frequency of multiple eration, of the recurrence of ulceration at fresh es, and of healed ulcers. These findings are especially portant when founded upon the investigation of the rts removed by gastrectomy, or even better when n in the live subject through a gastroscope (an strument which the author has frequently used in ese cases), for there can then be no suspicion of st-mortem effects. It is not going too far to state at almost all cases with prolonged histories afford idence of multiple ulcers, either active or healed. e are not dealing with a lesion of local origin but th some condition of the stomach which predisposes ulceration, and of which the ulcer itself is but a nifestation. The occurrence of jejunal ulceration er gastro-enterostomy for ulcer, and its absence er the same operation for carcinoma, favour the w that the contents of the stomach are responsible. e limitation of duodenal ulceration to the first rtion, where it is exposed to the stomach efflux, y be also evidence (admittedly equivocal) of portance of the contents. Yet the distinction tween wall and content is not perhaps so great as may seem, for the content is made up of two parts— ingested food and the added secretion from the ll. The evidence given in this article, although omplete, is in favour of a change in the contents the exciting cause of ulceration, and this can aceivably be brought about (1) by changes in the ture of the secretion, and (2) by changes in the food ten. Once again we meet the relationship between psin hydrochloric acid and ulcer, for increase of d secretion is the most constant and conspicuous ange in the contents. Why a stomach should rete these materials in excess is difficult to see; ne authorities, on the evidence of test-meals, deny at they are in excess, but the ordinary test-meal ly estimates the strength and not the quantities of d secreted. When all the clinical and experimental work is examined it must be admitted that the sociation between the two is so close as to resemble se and effect. Change in secretion, both quantitive and qualitative, is experimentally produced by erations in the nature of the ingested food. The ssical work of Pavlov showed that there is a ychical as well as a direct secretion, the former ing stopped by nerve section. The importance of psychical secretion in man is difficult to estimate, t it may be the secret of the alteration in gastric retion. It is certainly intriguing, and perhaps not olly fantastic, to assume that the flagging appetite civilisation, with its sedentary occupations and nomy of manual labour, is abnormally stimulated the consumption of highly flavoured and spiced ds with the plentiful addition of condiments. ese substances, including the extractives, are own experimentally to produce a copious psychical retion of gastric juice. Pepsin hydrochloric acid y therefore be produced in large excess of that ely to be absorbed by the meagre quantity of food ten. The acid curves after the usual test-meal of iel are not those which might be expected to low the ingestion of a full meal, nor would it be at easy to estimate the free acid in such a complicated xture. Duodenal ulcer is said to be commoner ong sedentary workers, and the symptoms are rticularly prone to recrudescence during periods of ntal strain and anxiety when the appetite fails; same may be said of the symptoms attributed to perchlorhydria without ulcer formation. This ory assumes that the stomach is constantly being ceived into producing more secretion than is needed, al in the course of time develops the habit of essive response. The success claimed for denervan operations may be partly due to the abolition of chical secretion, although simultaneous cutting-off the motor control and sensory supply renders finite conclusions impossible. The post-denervation test-meal curve given here shows little change, but of course it makes no pretence of representing the psychical secretion. If the habit of hypersecretion ultimately becomes an intrinsic function of the stomach denervation would produce little effect in established cases. So little is known, however, of the nervous control of the stomach in man and of the effects of denervation that it would be unwise to dogmatise.

Summary.

Ulceration should be regarded as a local incident in a much more fundamental general change in the functions of the stomach. This change, however produced, leads to the secretion of an excess of pepsin hydrochloric acid which may be regarded as the direct exciting cause of the ulceration. The acid may, in an uncertain and irregular fashion, be somewhat reduced by gastro-enterostomy; it can only be abolished by removal of the pyloric half of the stomach. Partial gastrectomy is the only operation which removes the cause of the ulceration in the majority of cases and which can be trusted to result in permanent cure. (Some may object to the use of this word when the affected part is excised.) This conclusion is amply borne out by the details given in this paper. The author has not quite enough courage in his convictions to subject to partial gastrectomy all cases of gastric and duodenal ulceration at whatever stage, but treats early cases upon medical lines in the hope that some change may thus be effected in the secretory activities of the stomach. In cases of simple duodenal ulceration of short history a partial gastrectomy appears unnecessarily severe when a safe gastro-enterostomy so frequently relieves the symptoms. This is perhaps not illogical, for in such cases the acid content is not always high and may therefore be sufficiently reduced by partial neutralisation. If the pre-operative test-meal reveals a high acid content it is probably wise, even in these cases, to perform a partial gastrectomy and so escape further ulceration, perhaps in the jejunum. For all other cases partial gastrectomy is the operation of choice, and, if the presence of adhesions, penetration of ulcer, or difficulty of access will obviously render the operation a difficult and dangerous one, the possibility of anastomosis of jejunum with the cardiac half of the stomach and the resection of the pyloric end at a subsequent operation, as in the Billroth 2 method, should be seriously considered. In this way an operation, otherwise serious, may be rendered comparatively safe. Where gastro-enterostomy has already been performed without relief of symptoms, partial gastrectomy holds out a very good hope of cure; indeed some of the most gratifying cases in the series come into this group. In the absence of jejunal ulceration it is sometimes possible to utilise the gastro-enterostomy aperture, the pyloric end being excised as in the Billroth 2 operation. Where the original anastomosis has been performed towards the pyloric end, or where jejunal ulceration is present, the whole is excised with the stomach and a fresh anastomosis made, usually by the Polya method. The former is a very safe procedure, but the latter may in some difficult cases demand the utmost dexterity and care.

Ulcers in the cardiac half of the stomach are not so uncommon as is sometimes thought. Where the ulcer is capable of local excision, without danger, this should be done, combined immediately or subsequently with partial gastrectomy. Where the ulcer cannot be excised removal of the pyloric end is nevertheless indicated. This method of treatment has been adopted in several cases with complete relief of symptoms, and definite radiographic evidence of cure of the ulcer.

No reference has been made to the actual cause of the pain, since this is outside the scope of the article. If, as is probable, it is due to irregular muscle tension and abnormal intragastric pressure (in the absence, of course, of penetration of surrounding structures), a partial gastrectomy must correct both, as it produces immediate relief of symptoms. Relief of symptoms, however, does not necessarily imply cure of the ulcer,

as shown by the cases of hæmorrhage and perforation which occur after gastro-enterostomy has produced complete relief of symptoms. For this reason special emphasis has been laid here upon the actual cure of ulceration and prevention of recurrence rather than upon the mere relief of symptoms.

I wish to acknowledge my indebtedness to Mr. E. Crook, surgical registrar, Charing Cross Hospital, who has taken infinite pains in the collection of the statistics and the carrying out of post-operative inquiries; to the staff of the Institute of Pathology for their chemical (Dr. J. Patterson) and pathological (Dr. A. B. Rosher and Dr. Berry) investigations, and to Dr. Russell Reynolds and Dr. Cochrane Shanks for the radiographic work.

THE STANDARDISATION OF SCARLET FEVER ANTITOXIN

BY CLINICAL METHODS.

BY ROBERT CRUICKSHANK, M.D. ABERD., D.P.H.,

MCROBERT RESEARCH LECTURER, UNIVERSITY OF ABERDEEN; FORMERLY ASSISTANT MEDICAL OFFICER, BELVIDERE HOSPITAL, GLASGOW.

THERE are four methods in use for the standardisation of the scarlatinal streptococcic toxin and antitoxin. Three of these are clinical tests for which the human volunteer is necessary; the fourth is a method, recently described by Parish and Okell, which tests the potency of scarlatinal antitoxin in protecting rabbits against the intravenous injection of whole cultures of *Streptococcus scarlatinæ*. Laboratory animals are relatively insusceptible to the toxin of *S. scarlatinæ*, and this last method, while it serves to "differentiate efficient therapeutic sera from inefficient," lacks the accuracy with which the dosage of diphtheria antitoxin, for example, may be estimated. Whereas 0·002 c.cm. of diphtheritic toxin is an average lethal dose for a guinea-pig, 20–40 c.cm. of scarlatinal toxin, representing 500 times the quantity of toxin which will produce the scarlatinoid syndrome in man, are required to kill a rabbit. Nevertheless, any laboratory method which may compete in accuracy with the clinical tests for the standardisation of scarlatinal antitoxin must be the method of choice for various reasons. The tests can be carried out by competent technicians in the laboratory where the toxin and antitoxin is being prepared; the supply of animals is not limited like the number of human volunteers, and the individual variability is probably much less in the rabbit than in man.

The three clinical methods by which standardisation of scarlatinal antitoxin may be attempted are: (1) by the utilisation of the Schultz-Charlton phenomenon; (2) by passive immunisation; and (3) by the so-called skin method. It is proposed to give a short description and discussion of the results obtained from the use of these methods, and to discuss shortly their relative merits and limitations.

The Schultz-Charlton Test.

The serum of an individual convalescent from scarlet fever, or artificially prepared scarlatinal antitoxin, injected into the skin of scarlet fever patients while the rash is still bright, causes a blanching of the skin at the site of injection. In the application of this phenomenon to the diagnosis of scarlet fever (using a 1 : 10 dilution of antitoxin) a positive reaction is evidence of scarlatina, but a negative result does not quite exclude the infection, since some scarlet fever rashes are not blanched. Moreover, the test is least reliable where its use is most indicated—namely, in faint and otherwise atypical eruptions. It has, however, a useful application in the standardisation and comparison of scarlatinal antitoxins.

Method.—In the performance of the test dilutions c 1 : 1000 to 1 : 32,000 of the sera were used, since an antitoxi which does not cause blanching in a dilution of 1 : 100 is of little therapeutic value. Children of 5 to 15 year with bright finely punctate rashes gave the best results the abdomen is the most suitable site for the tests, an 0·4 c.cm. of the serum dilution was found to be an appro priate dose for injection. Usually four tests were don on each patient: two different antisera were compared, an two dilutions of each were used. If, for example, a dilutio of 1 : 4000 but not 1 : 8000 of antitoxin A causes blanching and a dilution of 1 : 8000 of antitoxin B causes blanching the antitoxins can be standardised, and it is establishe that serum B has double the therapeutic value of serum A Two sera S.A. 4571 and S.A. 4462 in dilutions of 1 : 100(1 : 8000, and 1 : 16,000 were tested. Antitoxin S.A. 457 gave uniformly positive reactions in dilutions of 1 : 100 and 1 : 8000, but two only out of eight cases tested wer positive with a dilution of 1 : 16,000. S.A. 4462 produce blanching in a dilution of 1 : 1000 with all cases, but onl four out of sixteen and none out of eight patients whe tested with dilutions respectively of 1 : 8000 and 1 : 16,00 gave positive reactions.

Passive Immunisation.

To standardise and compare antitoxins by th passive immunisation of susceptible subjects one c two methods may be adopted: either (*a*) find th smallest dose of antitoxin which will render a Dick positive reaction Dick-negative in 24 hours in patient accidentally exposed to the risk of infection or (*b*) determine the duration of immunity conferre by the injection of a standard amount of the antitoxin The second method was used: 2·5 c.cm., 5 c.cm and in a few cases 10 c.cm. of the serum was injecte intramuscularly into patients who had given definit Dick-positive reactions; these individuals were the Dick-tested at regular intervals of time (24 hours 5, 8, 13 days), until they again became Dick-positive For comparison of the two antitoxins, the test subjects were as far as possible children of the sam age, giving Dick reactions of equal intensity. Eve then, a lack of uniformity in the results may b expected, for the amount of scarlatinal antitoxi already present in the blood is probably not the sam for any two individuals. For instance, the injectio of 5 c.cm. of antitoxin may protect one child for tw weeks, while an equal amount of the same antitoxi may protect another child with less natural antitoxi for one week only.* Table I. briefly summarises th results obtained.

TABLE I.—*Duration of Immunity with* (A) *2·5 c.cm and* (B) *5 c.cm. Antitoxin.*

The Skin Method.

The test subjects for this method of standardisatio must be, as in the passive immunisation metho susceptible to scarlet fever, and must give a Dic reaction of at least 20 mm. diameter with five skin-tes

* The utility of passive immunisation in affording immediat protection to susceptible individuals exposed to scarlet feve has been discussed elsewhere (Cruickshank, Glasg. Med. Jour. It may be said that in general 2·5 c.cm. of a concentrate antitoxin protects for 3–6 days, 5 c.cm. for 7–10 days, an 10 c.cm. for 2–3 weeks.

es of toxin. In hospital, patients convalescent from ntheria and chicken-pox, and accidentally exposed he risk of infection, were found most suitable for purpose.

ethod.—Measured volumes of the toxin diluted to contain skin-test doses in 0·2 c.cm. were mixed in vitro with equal ntities of antitoxin in dilutions of 1 : 100 to 1 : 1000. r standing at room temperature for one hour, 0·2 c.cm. hese toxin-antitoxin mixtures—each containing five -test doses of toxin—was injected intradermally; a rol test with toxin alone was also done. The mixture h reduces the reaction from 20 mm. in size to less t 10 mm. contains sufficient antitoxin to neutralise skin-test doses of toxin. The "therapeutic dose"—amount of antitoxin required to neutralise 20,000 skin-doses of toxin (Dick and Dick)—can be readily calcu-l. Two sera, S.A. 4627 and S.A. 4565, were compared. preliminary dilutions were made with graduated 1 c.cm. ttes, a separate pipette being used for each antiserum for the toxin, and again separate syringes were used the intradermal injection of the different mixtures. abdomen is the site of choice, since half a dozen or e tests can be done simultaneously and the reactions are e definite and measurable there than on the arms.

he results given in Table II. indicate that the eutralising" dilution of antitoxin is 1 : 100.

BLE II.—*The Skin Reaction to the Intradermal Injection of Toxin plus Varying Dilutions of Antitoxin.*

Size of Reaction in mm. Measured in Two Diameters.

ution anti-xin.	S.A. 4627.		S.A. 4565.		Toxin control. 24 hrs.
	24 hrs.	48 hrs.	24 hrs.	48 hrs.

100	—	15 : 15†	20 : 22†	20 : 25†	27 : 33

Each of these figures represents the average of four separate ions on four children.
With 1 : 100 dilution of antitoxin only one case showed any ion with both S.A. 4627 and S.A. 4565.

Discussion.

one of the three clinical methods under considera- gave results that were sufficiently delicate and orm to merit recommendation as an accurate and uble method of standardising scarlatinal antitoxin. s might a priori be expected, since the human subject es within wide limits in his response to infection; variation, where scarlet fever is concerned, is bably due, in part at least, to the variable amount natural antitoxin in the blood of different indi-uals. The difficulty could be surmounted by ng the average of a large number of individuals, unfortunately the supply of human volunteers is ted.

n a comparison of the tests, preference must be orded to that method which is the most delicate at the same time gives uniform results. In other ds, a method which will distinguish between the tralising power of dilutions of 1 : 100 and 1 : 200 n antitoxin, or between the antibody content of c.cm. and 5 c.cm. of a serum, is preferable to a hod which can only tell us that a dilution of 00 is more potent than one of 1 : 400 or 1 : 800, hat 10–20 c.cm. of a serum contains more antibody n 2·5 c.cm. The tables show that the results ined by passive immunisation best fulfil the irements, provided that the Dick test be repeated four- to five-day intervals. Taking antitoxin 462E (Table I.), for example, if the patients e Dick-tested only 24 hours after injection of the m it would be impossible to distinguish between protective values of 2·5 c.cm. and 5 c.cm., but t days afterwards, 14 out of 16 individuals iving 2·5 c.cm. were again Dick-positive, compared n four only out of 14 receiving 5 c.cm. of antitoxin. ortunately the passive immunisation method ires a prolonged observation of the test subjects with repeated Dick tests, and, in addition, the injection of serum, which may not be without attendant risks in a sensitised individual. The Schultz-Charlton test can be carried out only on patients with bright scarlatinal rashes. Apart from the small percentage of cases which fail to react to the test, the method gives results which are fairly uniform and delicate.

The skin method, in our hands, failed to differentiate a dilution of antitoxin of 1 : 800–1 : 1000 from a dilution of 1 : 200, so that on the standard of delicacy it failed. The method has certain advantages, however, in that it is fairly easy, the tests are done on susceptible subjects, who require to be under observation for two days only, and the results obtained were more uniform and clean-cut than with either of the two previous methods. It is the method recommended by Dick and Dick, and has been adopted as the official method of standardising scarlatinal antitoxin by the Hygienic Laboratory of the United States Public Health Service.

If these clinical tests be compared with the laboratory test of Parish and Okell, they appear to have some advantage in the differentiation of the relative therapeutic values of scarlatinal antitoxins, but the drawbacks to the clinical tests are such as to give the laboratory test the preference as the method of choice. It must not be supposed, however, that any of the methods at present available is sufficiently accurate to allow a uniformity in the dosage of scarlatinal antitoxin in any way approaching that of diphtheria antitoxin.

I am indebted to Dr. R. A. O'Brien, of the Wellcome Physiological Research Laboratories, for suggesting this piece of work and for advice throughout its course. Most of the material was supplied directly by him.

ÆTIOLOGY OF HYPERPIESIS IN EGYPTIANS.*

BY ABD-EL-AZIZ ISMAIL, M.R.C.P. LOND., D.P.H. LOND., D.T.M. CAMB.,
PHYSICIAN, KASR-EL-AINI HOSPITAL, CAIRO.

THE conclusions in this paper are based on a study of over 3000 cases, many of whom were traced for 10 to 15 years. All were seen in private practice, so that they were observed over a much longer period than is possible in a hospital; observations for short periods on a disease which seems to be lifelong are misleading, and give a false idea of its natural course.

Chronic primary hyperpiesis in the absence of chronic inflammatory renal changes is quite common in Egypt, and forms at least 10 per cent. of all cases in private clinics, but is rare in hospital practice. For four years, 1913–1917, not a single case was admitted, and in the following years only two genuine cases could be picked out. The disease is especially limited to the two decades 35–55, and is very rare under 30; the youngest patient was a student of 27 whose father and mother had both suffered from the disease, which appeared in him when he was 23. The condition is rare after 60, and the eldest patient was about 75. About 10 per cent. of the cases are females.

Out of 100 consecutive cases 37 were fellahin of the middle class, 17 were lawyers, judges, and mental workers, 10 were doctors, and 10 females; the rest came from clerical and other occupations, two being railway porters.

* Summary of several addresses given to Kasr-el-Aini Hospital Society and Egyptian Medical Society.

Diet, Nervous Influences, Toxins, and Infections.

That excess of food, especially protein, causes a hyperpiesia is undoubted. The rise is, however, temporary, and the pressure falls gradually and sometimes suddenly as soon as the intake is limited.

A young man of 30, weighing 72 kilos, developed pulmonary tuberculosis and was advised to over-feed. His blood pressure rose from an average of 100/75 to 200/100, and remained up for about six months, during which time his weight increased by 25 kilos. With limitation of diet and graduated exercise the pressure fell to 150/105 in the course of three months, and has remained there till now (three years).

Excess of diet plays a part in acute hyperpiesis in normal subjects or in extra rises (often temporary) in subjects of chronic hyperpiesia. That diet is certainly not the cause of the latter is shown by the fact that 40 per cent. of cases of high hyperpiesia were of normal weight or slightly under. Overfeeding and overweight is by no means always accompanied by rises of pressure, and in women of a certain class, especially at the climacteric, though overweight is common, less than one-fifth have hyperpiesia.

That strong emotional disturbance can cause marked rises of pressure is certain; the effect is, however, temporary, and in no single case was a permanent effect found.

A lady of about 50, previously in good health, with systolic pressure ranging from 120–140 for years, suddenly, after prolonged grief, complained of severe headache, congestion of the face, and asthmatic-like attacks at night. Blood pressure 310/160. No sign of local nerve lesion. Urea 30 mg. or 0·03 per cent. of blood; urine normal. Venesection and elimination treatment with bromides lowered the pressure to 200/100–240/110 in about six days, but the systolic pressure remained about 200 for at least two months in spite of treatment. On separation from her husband (apparently a great mental relief) the pressure fell to 120–150, and for the last year and a half there has been no return to the high figure.

Many similar cases were observed, and in all of them the pressure fell as soon as the nervous condition improved. Nerve storms are important causes of rise of pressure in normal subjects, of extra rises in hyperpietic cases, or even of onset. That they are not the sole cause is shown by the fact that fully one-third of the cases occurred in placid men and women of the middle class with sedentary habits, many of them unable to read or write and having no special complaint. Conversely, hyperpiesia does not necessarily follow emotional states.

That certain substances absorbed from the alimentary tract have a pressor action has been shown experimentally, and some—e.g., isoamylamine, P-hydroxy, phenylethylamine, and phenylethylamine—have been isolated. These and similar substances may be operative in acute cases of hyperpiesia, as shown by the rapid fall of blood pressure (often permanent) on elimination treatment and starvation. In chronic primary hyperpiesia the blood pressure is affected very little if at all by any method of treatment. Formerly, hyperpiesis was looked upon as an untoward sign in all cases, and every effort was made to lower it, including rest in bed for months at a time, repeated venesection, repeated doses of calomel and salines, and strict lacto-vegetarian diet with two starvation days per week. It soon became clear that the resulting fall was slight, and in some cases the pressure actually rose during the treatment—showing conclusively that the rise was not due to absorbed toxins, the amount of which should have been diminished by a very restricted régime.

A railway inspector was seen on several occasions in 1919 with average blood pressure 170/80 and nervous symptoms (fatigue and insomnia) suggesting neurasthenia. With absolute rest in bed and milk diet the symptoms markedly improved, but the blood pressure rose to 220/100. The patient remained in perfect health, and for the next three years his pressure ranged from 200–220. Since then nothing has been heard of him.

The course taken by chronic hyperpietics is a continuous one with few intermissions (extra rise or fall), which would certainly not be the case were the rise due to absorption of toxins, the amount of which would be subject to continuous variations. Ag toxins, whatever their nature, would give rise to o symptoms besides hyperpiesis, but these pati continue generally for years without any sympt at all; some have been traced for 15 years and s with a reliable medical history, for 25 years. Occasi symptoms, such as headache, giddiness, dyspr or asthmatic attacks, can be easily shown to hav relation to the chronic malady. They bear relation to the degree of hyperpiesis, and often o without extra rise of the blood pressure, and in s with a relative fall. They can be relieved by elim tive treatment, which does not affect the heigh the blood pressure, for this is in many cases hi after treatment than before. These symptoms due to absorption of substances with a pressor depressor effect, and have no relation to the orig disease.

An example is afforded by a patient with severe head following trephining for chronic glaucoma, unexpl by the eye condition. The blood pressure varied 220/110 to 230/130, and remained approximately at same height for six weeks; with blood-letting, elimina and starvation it dropped at times to 200, but the head did not disappear. Finally the headache disappeared s taneously, but the pressure has remained at about 240 with occasional rises, until now (2½ years).

Graver and more permanent symptoms w occur in hyperpietics are due to arterio-sclerosi its complications, and not directly to the hyperpi Much, however, may be said in support of the that arterial disease is secondary to the incre pressure.

Syphilis, at times suspected as a cause, certa has no relation to the disease; repeated course bismuth, mercury, and arsenic will change a pos Wassermann to negative without changing pressure. Temporary rises of pressure occu syphilitic subjects, as in normal subjects, but that no relation to the chronic malady.

A history of old infectious fever (typhoid, mal is quite common, but so high is the incidence of the infectious fevers and hyperpiesia that no c relation between them can be established. A not feature is the absence of ankylostoma and pell and, to a lesser extent, of bilharzial infection, dis which are very common in hospital class pati in whom hyperpiesia is almost non-existent.

Alcohol as a cause can easily be dismissed, a majority of patients had never tasted it. Tob seems to lower the tension, and some of the ma hypotensives were heavy smokers (over 40 cigar daily). Excess of coffee seems to be responsibl temporary rises of pressure in normal individuals hyperpietics. No causal relationship can, how be drawn between the amount of coffee taken an degree of hyperpiesis. Some of the marked hyp sives were patients who consumed 40 cups (4·0 g. caffeine) for years, and fully one-third cases of hyperpiesia drank no coffee, or less tha cups daily (1·0 g. caffeine).

The Family History.

The disease is hereditary and social, and in cases familial. In 100 consecutive cases 72 h history in the father or mother, brothers or si uncles or aunts, suggesting death from one o complications of the disease—e.g., a hemipleg death suddenly after a meal (angina pectoris) attack of dyspnœa or fatal epistaxis. This gene occurs in the fifth and sixth decade, and is well k amongst the middle class, who are the chief suff and often a man will come for examination f other complaint than that his father or mother from or was affected with hemiplegia.

In some cases notable family histories occur—e merchant in Upper Egypt (Mallawy), aged 55, seen a ago. His blood pressure ranged from 180/100 to 20 His father died about the age of 60 with coma and plegia; his mother died, when over 60, with hemip Three brothers, aged respectively 50, 48 and 44, all sh pressures between 160 and 200 on several occasions.

Another marked example was that of a merchant af with the disease, whose father, mother, two sisters, an

thers were all affected (except one brother who had umatic endocarditis).

As a control the family history of 100 consecutive es of other ailments was taken, and only 25 per t. gave a history of father or mother being affected h symptoms suggesting hyperpiesia.

ie Relationship between Hyperpiesis and Diabetes.

n families where only one member is affected with perpiesis, a clear history of diabetes is often given, l sometimes some members of a family are affected h diabetes, some with hyperpiesia, and some with h. The relation between diabetes and hyperpiesis very close. Both are diseases of the middle and per classes, and very rare in the poor-class hospital ient. Both run a very long course, and for years re may be no symptoms in the absence of compli- ions. The chief age of onset in both diseases is n 30–40, and the duration of both is approximately same. The majority of hyperpietics die in the ies and 'sixties; diabetics, having better treatment, erally die in the 'sixties or 'seventies. The age onset and duration account for the rarity of perpiesia above 65 and of diabetes above 75. ongst several thousands of hyperpietics seen in years I can only recall nine cases above 65, includ- two between 70 and 80. The same statement ds good for diabetics, if allowance is made for htly increased longevity. Both diseases run their rse in spite of any treatment. This is certainly e of hyperpiesia, and was true of diabetes before days of insulin and regulated diet. Except in te crises treatment of hyperpiesia is useless, and imes dangerous; the rise of pressure is certainly pensatory. Attempts to lower the pressure by esection, elimination, vaso-dilators, diet, &c., were he majority of cases unsuccessful, and in those in m it was lowered temporarily symptoms arose ebral, renal or cardiac), apparently due to the mia which only disappeared on resumption of vious habits. The patient has to choose between ightly prolonged and restricted life and a useful, arently normal, short one, often terminated denly by fatal cerebral hæmorrhage, angina or mic-like symptoms. I certainly do not agree h Clifford Allbutt when he says: "If we catch erpiesis early and keep at work against it, it can cured more often than not."[1] Hyperpietics who not die from complications end with uræmic-like ptoms of auto-intoxication, analogous to diabetic ia. The similarity is so great that I surmise t hyperpiesis is due to a metabolic disturbance scrasia), often inborn and hereditary. Nothing nown about the relation of this disorder to ductless ids. A full trial of thyroid and parathyroid was le for months, and sometimes for years, in suspected s, and the results, though encouraging in a small ber, can only relate less than 2 per cent. of all s to deficiency of internal secretions. One thing ns certain, and that is the relation of the hyper- is to the metabolic change; the rise of pressure ntirely compensatory, and as long as the pressure elatively sufficient no symptoms arise, and the vidual enjoys normal habits. Only when the sure begins to fall do symptoms appear referable he metabolic dyscrasia.

[1] Clifford Allbutt, Diseases of the Arteries, vol. ii.

WESTERN OPHTHALMIC HOSPITAL, MARYLEBONE, AS "DANGEROUS STRUCTURE."—This hospital has been served a "dangerous structure" notice by the district sur- or of Marylebone on the ground that the building ght collapse at any moment like a house of cards," its demolition has been begun. Great difficulty has experienced in finding accommodation for the patients, f whom are awaiting operation. The hospital is an old gian building in the Marylebone-road, very cramped inconvenient, with wards the size of small bedrooms. operating theatre is only a few feet square with a floor ough boards, and a roof which leaks in wet weather; e are no facilities for moving patients after operations. ebuilding scheme to cost £40,000 was prepared some ago, and £23,000 has so far been collected.

Clinical and Laboratory Notes.

A NOTE ON BLOOD CHANGES ASSOCIATED WITH LIVER DIET IN YOUNG CONVALESCENTS.

BY K. SHIRLEY SMITH, M.B., M.R.C.P. LOND.,
MEDICAL REGISTRAR, MIDDLESEX HOSPITAL;
AND
L. E. H. WHITBY, M.D. CAMB., M.R.C.P. LOND.,
ASSISTANT PATHOLOGIST TO THE HOSPITAL.

IN order to find out whether the blood changes obtained with liver diet in cases of pernicious anæmia were confined only to that disease, it has been thought worth while to study the blood changes produced by the same diet in hospital patients free from any blood disease. Whereas the original work of Whipple indicated that liver diet was likely to be useful in all forms of anæmia, the first recorded results with liver diet in pernicious anæmia suggested that it was most specific for pernicious anæmia and exerted its maximum effect only in that disease. Recently it has been found by Vaughan[1] and others that some cases of secondary anæmia respond to liver treatment, and we have found that relatively normal children show a transient but definite stimulatory response to liver feeding.

The 11 cases selected for treatment in this investigation were between the ages of 3 and 15 years with the single exception of one girl aged 19. The majority of the patients were in surgical wards and were, during the experimental period, convalescing from such surgical conditions as inguinal hernia, tuberculous adenitis, and submaxillary abscess; others were in medical wards under treatment for such diseases as mediastinal adenitis and oxaluria. On account of the special interest attaching to the blood changes observed in them two cases are included in which the lymphatic system seemed principally affected; these were cases diagnosed as Hodgkin's disease and glandular fever.

Fresh cooked liver was given daily, the amount varying with the age of the patient; the older patients received 3 oz. daily and the younger ones 2 oz. A blood examination was made in every case before starting the diet and the feeding was continued for periods varying between six and 40 days. In the first few cases examinations were made at intervals of three or four days for a period of three weeks, but experience showed that the maximum effect was noticeable after about six days and that it declined thereafter. In no case was hæmatinic drugs given during the time of liver feeding.

The table shows the results with the 11 patients. In most cases the changes in red and white cell counts and in the hæmoglobin percentage have been included, whilst the alteration in the differential leucocyte count are recorded in all. The last two columns show the variations in the granular and non-granular cells in order to contrast the changes in bone-marrow cells with those taking origin from some source other than the bone-marrow. Such observations as were made on the red cells and hæmoglobin show that these tended to increase. A leucocytosis was produced in seven out of the 11 cases. In seven cases also there was an increase in the relative and absolute number of polymorphonuclears. Neither the increase in the total leucocytes nor the increase in polymorphonuclears was maintained for longer than ten days. Lymphocytes showed a relative but not absolute reduction in nearly all cases. A definite absolute increase in eosinophils was produced in all instances, the striking figure of 61 per cent. being found in the case of Hodgkin's disease. An increase in granular or bone-marrow cells was also the rule.

[1] Vaughan, Janet: THE LANCET, 1928, i., 1063.

These results show that the administration of liver to patients who suffer neither from pernicious anæmia nor any other blood disease produces alterations in the blood comparable to those occurring in the treatment of pernicious anæmia. An interesting feature of the series is the eosinophilia which has been also found in pernicious anæmia by one of us (L. E. H. W.),[2] and in secondary anæmia by Vaughan.[1] The definite increase in the red cells and bone-marrow leucocytes shows that liver must exert a stimulating action on the bone-marrow. It is difficult to believe that stimulation is the only action in pernicious anæ though evidently it is one essential feature.

We are inclined to suggest that liver is rich i substance essential for the proper functioning of bone-marrow; in pernicious anæmia, this substa whatever it may be, is not absorbed in suffici quantity from an ordinary mixed diet, perhaps account of the achlorhydria, though it is possible assimilate enough with massive liver feeding.

We are indebted to Dr. C. E. Lakin, Dr. E. Cockayne, and Mr. E. L. Pearce Gould for the clin material.

[2] THE LANCET, 1928, i., 285.

A COMPARISON OF THE "TITANIUM RAY" WITH THE METALLIC TUNGSTEN ARC.

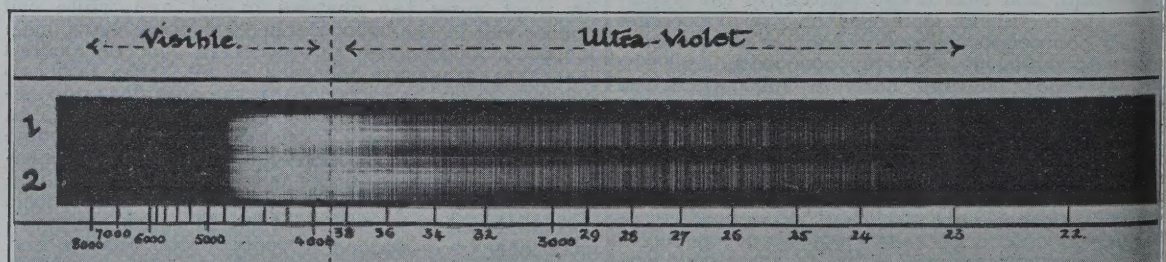
BY B. D. H. WATTERS, M.Sc.

(*From the Physics Department, Middlesex Hospital.*)

CONSIDERABLE interest has been aroused recently by a new arc designed for therapeutic work which is termed the "titanium ray." The arc is formed between metallic electrodes which consist of a tungsten alloy containing, it is claimed, approximately 4 per cent. titanium.

Titanium is a rare metal which occurs in small quantities in a large number of ores, and hence is often present in different metals as an impurity. The characteristic arc spectrum of the metal has a number of intense lines in the ultra-violet region. Samples of the electrodes supplied for generating this arc were obtained and the arc spectrum tested by means of a Hilger quartz spectrometer. For purposes of comparison, the spectrum given metallic tungsten of the quality used in therapeu work was included on the same plate. The pho graph of the two spectra is shown in the illustrati and it will be seen that they are practically ident both in the range of the ultra-violet and the dis bution of the intensity. Detailed examination the plate under a low-power microscope sh certain minor lines as more intense in the "titani ray" spectrum than in that given by commer tungsten. These variations are, however, so sli that the difference in the quality of the radiat from a therapeutic point of view must be conside as negligible.

The print reproduced here was obtained fron single plate containing the spectra of the two sour



The upper spectrum (1) is that of the "titanium ray" and the lower (2) is that of the tungsten arc. Exposure in each cas 30 seconds. (Photographed on an Ilford Process Plate.)

An incandescent filament lamp was used for printi and the distance of the lamp from the plate adjusted so as to bring out the full range of radiations.

A further test was made of the intensity of radiation from the two arcs judged by the product

erythema on the skin. Two small areas of skin ose together on the forearm were exposed consecutively to the arcs running under identical nditions as far as could be done. (Current, ampères; P.D. across electrodes, 58 volts; voltage supply drawn from a bank of large accumulators, 0 volts.) Three distinct pairs of exposures were ade on different days and in each case the erythema oduced by the "titanium ray" and the tungsten c could not be distinguished in depth of coloration d the latent period between the exposure and the pearance of the reaction was the same.

It has been stated that the "titanium ray" is ore penetrating than other sources of ultra-violet ht, but, judging from the evidence of the experiments scribed above, the penetration of the radiation can no different from that of other sources with a nilar spectral distribution.

A CASE OF
ABSCESS OF THE HEART CAUSING DEATH THROUGH CORONARY HÆMORRHAGE.

By Francis McLagan, M.B. St. And., D.P.M.,
ASSISTANT MEDICAL OFFICER, CANE HILL MENTAL HOSPITAL, SURREY.

A case of abscess of the heart apparently resulting m staphylococcal infection of the skin, and without idence of general pyæmia, is so rare that its descripn seems to be justified. Not only is the occurrence common, but in the case reported death was due rupture of the abscess into one of the coronary eries and the pericardial sac, giving rise to a ndition which simulated, and was at first mistaken cardiac rupture.

The Case Described.

A married man, aged 57, was admitted to hospital under tificate on Jan. 30th. Previous to certification he had n in poor health for some time and his latest occupation l been the somewhat arduous one of labourer. During multifarious pursuits—principally as soldier and stoker e had contracted malaria in Upper Burma and suffered m sunstroke in India many years previously. His dition on admission, however, was not thought to be sequent on these misfortunes. His personal history, related by his wife, showed him to be a man of temperate bits who, four years previous to admission, became weak, s subject to numerous boils and carbuncles, and developed mors of the legs.

On admission he exhibited many old scars, the result boils and carbuncles in the region of the back and legs, only one scar on the upper part of the body, and that the right shoulder. His chest was fairly well covered, the excursions on respiration were limited. No normality of the lungs was apparent on percussion, but auscultation râles and rhonchi were heard to such an ent that the heart sounds were obscured. The apex-t was 2 in. outside the nipple line, and the left border the heart was found in a corresponding position. His erial system, as judged from palpation of the radial ery, exhibited marked atheromatous and senile changes. was very unsteady on his legs and walked with a very le gait, and on examination of his reflexes it was found t his knee-jerks were very brisk and exaggerated.

As the mental disturbance has no bearing on the point ler consideration, a detailed account of his psychosis be omitted. It is considered only sufficient to state t although his memory was greatly impaired, he suffered n no delusions or hallucinations, and he was capable appreciating pain or distress and communicating his sations to those in attendance.

On Feb. 18th he developed a large carbuncle over the t trochanter, was put to bed, and received appropriate tment in the form of free drainage. The carbuncle ponded well to treatment, but three days later (Feb. 21st) oil appeared on the left hip. This, however, had healed March 7th, but the original area, although clean, had not sed. On March 12th another carbuncle appeared on the t buttock and several others appeared in a few days in region of the hips, buttocks, and sacrum. On the ning of March 30th the patient conversed as usual with medical officer and complained of no unusual symptoms, at 12.5 A.M. on the following day it was reported that seemed to have had a "seizure" and had collapsed. en seen by the medical officer he was found to be in remis, and despite treatment he died at 12 20 A.M.

The Wassermann reaction of the blood and cerebrospinal fluid was negative.

Post-mortem Findings.

At autopsy marked atheroma was apparent in all areas of the body with consequent cerebral softening; enlargement of the cerebral ventricles and increased submeningeal fluid.

The heart was enlarged, weighing 530 g., and showed marked myocardial hypertrophy with fatty degeneration; these latter pathological changes were most apparent in the left ventricle. The cardiac valves appeared normal, apart from slight atheromatous changes, and gave no evidence of vegetations or acute inflammation. The pericardial sac was filled, but not distended, with a soft blood-clot and a small tumour in the region of the great vessels. The tumour formed a small protuberance ½ in. in diameter and projected about ¼ in. from the surrounding heart wall. It was found on examination to be softer in consistency than the normal muscle, and one small channel was discovered through which a probe could be passed into the right coronary artery ½ in. from its origin in the sinus of Valsalva. On making a cross-section of the growth a loculus was encountered containing about 1 c.cm. of pus; unfortunately, no culture media was at hand and the nature of the causative organism remains in doubt.

All the other organs of the body were carefully examined and no evidence of pyogenic infection was discovered other than the cutaneous lesions already described, and pyorrhœa alveolaris. The viscera, apart from the lungs which were passively congested, showed degenerative changes subsequent to the impaired blood-supply brought about by the atheroma.

It is presumed that the condition was one of multilocular abscess (carbuncle) of the heart wall in which the pus had tracked, in one of the loculi, in two directions—to the coronary artery and to the pericardial surface of the heart. In this manner a channel had been formed through which the blood had flowed into the pericardial sac, producing a mechanical resistance to an already greatly weakened heart and so caused death.

I wish to express my thanks to Colonel S. C. Elgee, medical superintendent of Cane Hill Mental Hospital, for permission to publish this case.

Public Health Services.

THE HEALTH OF LONDON IN 1927.

Dr. F. N. Kay Menzies, in his report on the County of London for the year 1927, explains that in recent reports the general public health services have been extensively dealt with, and that in the present instance he has devoted more attention to the school medical service, which, "joining hands with social agencies, is more intimately in touch with the domestic lives of the people, and in this way exercises a material influence on the general public health."

General Health Services.

Statistics.

The Registrar-General's estimate of the population was 4,550,000, including 9000 non-civilians. The 73,263 births gave a birth-rate of 16·1 per thousand. In 1901, when the population was about the same, the births were 57,829 more. The death-rate was 12·1, as compared with 11·6 in the previous year, and the increase was almost entirely due to the influenza epidemic at the beginning of the year, which caused an increased mortality at the higher ages. Fatal street accidents caused 669 deaths as compared with 656 in the previous year, but the deaths of children under 15 were 14 less. The weather favoured infant life, and a decreased mortality from diarrhœa produced an infant mortality-rate of 59, the lowest ever recorded in London. The death-rate from phthisis was 0·91; from all forms of tuberculosis, 1·05; from cancer, 1·49; from pneumonia, 1·0; from bronchitis, 0·83; from pneumonia, bronchitis, and influenza combined, 2·23; and from diarrhœa and enteritis under two years, 7·6 per thousand births, to be compared with 12·0 in 1926.

The table for the metropolitan boroughs, excluding the City, shows that the lowest infant mortality-rates were recorded in Holborn (38), in Woolwich (42), and in

Lewisham (46); while the highest were in Paddington (79), Chelsea (76), and Shoreditch (74). From phthisis, the lowest rates were in Hampstead (0·44), in Kensington (0·65), and in Paddington (0·67); the highest were in Finsbury (1.36), in Bermondsey (1·22), and in Holborn (1·21). The lowest rates from pneumonia were recorded in Woolwich (0·67), Wandsworth (0·67), Hampstead (0·70), Greenwich (0·73), and Battersea (0·73); while the lowest rates from bronchitis were in Chelsea (0·50), Hampstead (0·59), Stoke Newington 0·59), and Hackney (0·60). The lowest rates from cancer were in Holborn (1·18), Shoreditch (1·27), and Bethnal Green (1·29); while the highest were in Chelsea (2·21), Hampstead (1·86), and Kensington (1·84). The puerperal fever incidence per thousand births was 3·57 for London and varied much among the boroughs, being lowest in Deptford (0·53), Kensington (1·13), and Stoke Newington (1·37); and highest in Chelsea (8·2), Fulham (6·98), and St. Pancras (6·68).

Dr. Menzies points out that the mortality from puerperal fever is much lower in boroughs with poorer-class populations, than in those populated largely by the well-to-do. Thus in the years 1921–25 the rate in the aggregate population of Bermondsey, Bethnal Green, Finsbury, Stepney, and Shoreditch was 0·88 per 1000 births, as compared with 1·80 in the aggregate population of Hampstead, Kensington, Lewisham, Stoke Newington, and Wandsworth. In 1927 the mortality from puerperal fever in London was 3·22 per thousand births among single women, as compared with 1·15 among married women, while the rates from other accidents of childbirth were 2·93 and 1·46 respectively. The suggestion is made that the statistics of maternal mortality from childbirth should be given for legitimate and illegitimate births separately.

Small-pox.

There were 5 cases of small-pox in the county. One case was of the mild type and imported from the north of England. The other 4 cases were apparently connected with an outbreak in Hendon which took place in March to May from some unrecognised source. This outbreak included 13 cases, of which 7 were fatal, including 2 of the 4 London cases. The first case of this outbreak was a man of 47, vaccinated only in infancy and his illness was considered to be chicken-pox. As the result of this failure in diagnosis, clothes were sent to the laundry and further cases occurred among the laundry workers, 4 of which proved fatal.

Anthrax.

During the first week of January 4 cases of anthrax occurred in connexion with the Zoological Gardens. All of the patients had been engaged in handling the carcasses of two elephants which had died from an illness the nature of which was not recognised until after the men were infected. Anti-anthrax serum was promptly administered and all the patients had fairly mild attacks. A prophylactic dose of serum was also given to 29 persons who had been in contact with the carcasses and no further cases occurred.

Encephalitis Lethargica.

There were 149 notifications of encephalitis lethargica, of which 114 were considered to be true cases. Of these, 49 had proved fatal up to March 31st, 1928.

A table indicates the present condition as regards 528 cases of encephalitis which came under observation from 1925 to 1927. Of these, 132 under the age of 16 and 111 over the age of 16 are stated to have recovered. Since November, 1925, the M.A.B. have provided 100 beds for children between the ages of 3 and 16 suffering from the after-effects of encephalitis. At Winchmore Hill Hospital Dr. G. A. Borthwick, the medical superintendent, has recently reported that this experimental unit has not been productive of curative results, but has proved valuable for observation purposes. It has also housed children whose mental condition unsuited them for outside life. In most cases he considers that the nerve-cells have been irretrievably damaged, but in a minority it may possible by patient endeavour to educate other ce to function in the place of those destroyed. While cannot recommend the Board to continue the secti as an experimental unit with curative hopes, the ne for housing these difficult and pitiful cases may sufficient justification for carrying it on.

Cancer.

An analysis is given of the deaths from cancer London during the period 1911 to 1920. The deat are divided into three groups. In group 1, comprisi growths of the upper alimentary tract, the death-r per million among males was 336 as compared with among females. In group 2, comprising growths the reproductive system, the female death-rate w 509 and the male rate 52. In group 3, wh includes all other cancers, the sex-incidence w approximately equal. The excessive female mortal in group 2 is shown to occur at an earlier age than t excessive male mortality in group 1. Some of t conclusions drawn from this analysis are: (1) th among persons over 35 the movements of the can mortality from 1850 onwards are correlated with t year of birth and not with progressive changes conditions of life; (2) that if this same correlat holds in the future, the female mortality-rate w continue to decline while the male rate will incre further for some time; and (3) that a cancer diathe may be the dominating factor and that the solution the cancer problem may ultimately be found to depe upon the detection and modification of such diathe

Tuberculosis.

During 1927 2305 samples of milk from 32 count were taken at London railway termini. The bacte logical examination was completed for 1969, of wh 154, or 7·8 per cent., yielded tubercle bacilli, as agai 4·5 per cent. in 1926. Information was sent to county medical officers of health and as a result cows were slaughtered under the Tuberculosis Orc In the case of 311 of the samples, the inocula guinea-pigs died from an acute infection, and notic this was also sent to the medical officers of health the chance of its being due to unsatisfactory conditi in the cowsheds. The conditions of patients w received residential treatment under the coun tuberculosis scheme are investigated after the la of five years. Adult cases treated in 1921, number 3178, were investigated. Of 468 pulmonary ca without tubercle bacilli, 83·5 per cent. were alive; 330 early cases with tubercle bacilli, 61·5 per cent. w alive; of 1299 moderately advanced, 34 per c were alive; of 858 advanced cases, 3·7 per cent. w alive; and of 223 "surgical" cases, 73·5 per c were alive. The particulars as to children under were as follows: Of 271 pulmonary cases with tubercle bacilli, 90 per cent. were alive; of early c with tubercle bacilli, 44·5 per cent. were alive; o moderately advanced, 50 per cent.; and of 33 advan 3 per cent. were alive. Of the 189 children treated non-pulmonary tuberculosis, 153 were alive, of wh 71 were at school and 58 at work.

In 1926 arrangements were made to try artifi light treatment in connexion with the dispensa The number of cases treated has been small but results have not been encouraging, and it is sugges that the best results will only be obtained in reside institutions. The scheme, however, is to be contin for another year. With the help of the Invalid Chil Aid Association, 146 children living in contact w advanced consumptives were boarded out in country. The arrangements for residential treatm for children have been improved and there is now waiting-list either for pulmonary or surgical cases.

Venereal Diseases.

The new cases of syphilis were 357 and the cases of gonorrhœa 813 in excess of the figures 1926. Although a number of patients still fai complete the full course of treatment, the ratio attendances has gone up to 40 per new case.

nber of non-venereal cases who present themselves examination at the clinics has shown a steady rease. Thus in 1917 the non-venereal cases numbered ut one-sixth of the venereal. In 1922 they nbered about one-third, and in 1927 they numbered re than one-half. The practitioners qualified for supplies of salvarsan, &c., now number 446, compared with 108 at the end of 1917.

School Medical Service.

The school report indicates a steady progress of the provement programmes dealing with the reduced of classes, improved desks, and sanitary conditions. ere is even a revolt against desks altogether. ant departments are already equipped with table l chairs instead of desks.

Rheumatic Children.

Dr. J. Nairn Dobbie has continued his investigations h regard to rheumatic children. His material was cases admitted under the council's scheme to shalton or Highwood hospitals. Of these children, were below the average in nutrition; while 19 wed no evidence of heart affection, 42 were uspicious," and 39 definitely affected. The tonsils e seldom markedly enlarged; adenoids were not a eworthy feature, and the children did not belong the "catarrhal," but rather to the nervous type. ir educational attainments were below the average. 44 cases the parents stated that the children had n "nervous" all their lives, and Dr. Dobbie ours the view that this nervousness is inherited. In there was history of rheumatic incidence on the nmediate" family, and in only 23 was there no umatic family history. The homes of 35 were ms and of 53 more semi-slums. Dr. Dobbie's pression was that the actual dampness in most of houses was of small degree. In the case of such nes the washing of clothes is done at the public hs. To sum up the environment: "It would pear that no one disadvantageous factor stands out, rather that each and all of the concomitants of verty, poor houses, dampness, unhealthy sites, ercrowding, lack of ventilation and of sunlight, poor ding, poor clothing, irregular habits, &c., destruc-ely converge on these unfortunate children, who t along the lines their bias carries them, be it rasmus, rheumatism, tuberculosis, or the respiratory eases generally."

Nursery Schools.

A special report deals with nursery schools in ndon, Manchester, and Bradford. At the outset it is nted out that the medical objections to a large ool—e.g., the McMillan with an average attendance 220—have been overcome. These schools are needed st for the *most* neglected children from the worst nes. There should always be some bathing accom-dation and an open air régime. The social function the school is twofold; it trains the children and by ucating the mothers, raises the home life to a her level. "The potential under dog, rebel, or archist can be recognised among the entrants to nursery school, but it is seldom they are not nsformed into orderly, active, and happy citizens of ir community." Educationally, no attempt is de to teach the three R's, and the most profitable rsuits are rhythmic movements, speech training, and nd work. Special training is needed for the staff d there is at present a dearth of such training ntres. To be drawn to the work is not enough. The nursery school teacher must not only be a lover children, but a knower of children as well, and a ower of all the factors that make for health, owth, and happiness." The nursery school must velop its own methods and create its own traditions, d must not be absorbed into elementary education til it is strong enough to reform the infant school m the bottom. The education of the younger pupils s hitherto suffered too much from academic and okish traditions proceeding from the top.

Dr. Menzies takes exception to the statement of the ief medical officer of the Board of Education that London is an area without an orthopædic scheme. He shows that the council has not neglected its duty to the crippled children of London despite the disadvantage that it is not the local authority under the Maternity and Child Welfare Act. He also gives reasons to show that the percentage of children who leave the physically defective schools of a district wearing apparatus is not a satisfactory index of the efficiency of the district's orthopædic scheme.

Mr. Sowden Hills, inspecting dental surgeon, has completed a comparison of English and Jewish children as regards dental condition. About 7000 children were examined. He finds that up to the twelfth year there is no marked divergence, but that after this age the English boys show an increase in the amount of dental decay while the Jewish boys show a decrease.

MENTAL HOSPITAL REPORTS.

The *City of Leicester Mental Hospital* at West Humberstone had 941 patients on its books on March 31st, 1928. The ratio of mentally afflicted in Leicester is now 1:304; ten years ago it was 1:338. The recovery-rate for 1927 was 45·66 per cent. and the death-rate 6·31 per cent., figures which compare very favourably with the average for all public mental hospitals. Autopsies were held on 90 per cent. of those who died. Leave of absence was granted on 2870 occasions, and 52 per cent. of men and 37 per cent. of women patients have full or limited parole. Only 13 temporary and 3 permanent escapes resulted from this liberty. Small parties go out regularly for motor drives and to the cinema, and 78 per cent. of the patients are usefully employed. A cinematograph was installed in the recreation hall in the autumn. The old house of the medical superintendent has been converted into a female block; 32 new beds will be provided at the very low cost of £64 per bed. A new nurses' home is to be built. Two more members of the staff have obtained their M.P.A. certificate. A "Trinity" ultra-violet ray outfit has been installed in the X ray department. The pathologist reports on the malarial treatment of 12 more cases of general paralysis. Only one non-paralytic patient showed any improvement after induced malaria, but of 48 paralytics 25 per cent. have been discharged recovered and another 14·5 per cent. are "much improved." Reduction of the globulin and cell content of the cerebro-spinal fluid has been noticed, and in several cases the colloidal gold curve has changed to the luetic type. The investigation into the incidence of syphilis shows that of 218 males 7·5 per cent. and of 286 females 4·9 per cent. gave positive Wassermann reactions. The dental surgeon reports 347 operations, 99 inspections, and 27 refusals of treatment. All new admissions are inspected by him. The oral condition in general shows steady improvement.

The *City of Worcester Mental Hospital* at Powick housed 1056 patients at the end of last year. The discharge-rate was 43·52 per cent. and the death-rate 7·12 per cent. Post-mortem examinations were made in 65·75 per cent. of instances. The general health was good save for influenza and one case of erysipelas. Three babies were born in the hospital; two of the mothers have since been discharged. The new verandah for male patients fills a long-felt need, but the hospital still lacks clinical rooms, an admission block, and a convalescent villa. A continuous bath has been installed in one of the female wards. Thirty-three patients went out on trial, and 38 had parole within the estate. Six nurses obtained their M.P.A. certificate.

The *City of London Mental Hospital* at Stone, Dartford, had an active year in 1927. Of the 161 patients admitted 72 came on a voluntary basis. The recovery-rate was 30 per cent. for the certified and 40 per cent. for the voluntary patients. The death-rate was 5·86 per cent. There were 398 private and 246 rate-aided patients on the books at the end

of the year. There was not a single case of infectious disease, and the general health was good. Parties of rate-aided patients were sent to the seaside. Tiresome patients are now segregated in Newstone House, and the female infirmary ward has been divided so that recent admissions can be treated apart from other inmates. The new single rooms are furnished like ordinary bedrooms, and every possible parole is allowed. Two new wireless sets and two more ultra-violet ray lamps have been installed. The farm continues to supply all the milk, mutton, pork, eggs, poultry, and vegetables required for the hospital. A small dairy has been built and equipped. A difficulty in obtaining female nurses has now been satisfactorily overcome, and one more attendant has obtained his M.P.A. certificate. Fourteen men and 11 women nurses are now registered or certificated. The consulting staff now comprises a physician, a surgeon, a gynæcologist, an ophthalmologist, and an aurist. The Minister of Health visited the hospital in the autumn.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 28TH, 1928.

Notifications.—The following cases of infectious diseases were notified during the week:—Small-pox, 149 (last week, 173); scarlet fever, 1641; diphtheria, 926; enteric fever, 83; pneumonia, 654; puerperal fever, 54; puerperal pyrexia, 84; cerebro-spinal fever, 8; acute poliomyelitis, 8; acute polio-encephalitis, 2; encephalitis lethargica, 28; continued fever, 1; dysentery, 5; ophthalmia neonatorum, 118. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified in the following 17 counties: London, 3; Derby, 17; Devon, 3 (Plymouth); Durham, 38; Huntingdon, 1; Lancaster, 1; Leicester, 2; Norfolk, 2; Northampton, 2; Northumberland, 7; Nottingham, 5; Stafford, 11; Yorks, East Riding 6, North Riding 2, West Riding 23; Glamorgan 10; Monmouth, 15; and 1 at the Port of Southampton.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on July 31st–August 1st was as follows:—Small-pox, 19 under treatment, 1 under observation; scarlet fever, 1743; diphtheria, 1791; enteric fever, 39; measles, 323; whooping-cough, 194; puerperal fever, 18 (plus 11 babies); encephalitis lethargica, 71; poliomyelitis, 2; "other diseases," 20. At St. Margaret's Hospital there were 20 babies (plus 15 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox or enteric fever, 19 (5) from measles, 2 (1) from scarlet fever, 32 (5) from whooping-cough, 22 (3) from diphtheria, 53 (11) from diarrhœa and enteritis under two years, and 25 (7) from influenza. The figures in parentheses are those for London itself.

Of the 14 fatal cases of measles outside London, 9 were reported from Liverpool and 3 from Birmingham. Of the 27 fatal cases of whooping-cough outside London, 8 were reported from Liverpool, 5 from Birmingham, and 4 from Newcastle-on-Tyne. The deaths from diarrhœa were about 50 per cent. more than in the previous week.

The number of stillbirths registered during the week was 276 in the great towns (corresponding to a rate of 39 per 1000 births) including 39 in London.

Paratyphoid in the London Area.—The figures given above record a large increase over the previous week in the notifications of "enteric fever" and in the number of admissions under this head to M.A.B. hospitals. Since the return was made up upwards of 100 cases of paratyphoid B. infection have been notified in the London area, the cases for the most part being of a mild type, although one fatal result has been reported. The wide distribution suggests the infection of some common article of food, cream being under suspicion rather than the milk or water supply. The most intense centres of infection have been in Epsom and Kensington, although Wandsworth, Fulham, and Westminster have borne their share. The outbreak has been somewhat confused in the popular mind with a group of cases of food poisoning of a very different type among police officers in the Westminster area with a fatal case of toxæmia, in which death was presumed to have resulted from eating infected ham; the pathological report from King's College Pathological Laboratory confirmed this finding, but the inquest has not yet been concluded.

Reviews and Notices of Books

THE PRESCRIBING OF SPECTACLES.

Third edition. By ARCHIBALD STANLEY PERCIV M.A., M.B., B.C. Cantab. Illustrated with d grams. Bristol: John Wright and Sons, L 1928. Pp. 239. 15*s*.

THIS book, which is written by an acknowled authority on mathematical optics and on the minutia spectacle prescribing, has been rewritten and enlarg It contains much interesting matter besides the us accounts of the optics of refraction and of the meth of testing the refraction of the eye. For retinosco the concave mirror is recommended on the grou that illumination is better than with the pl mirror; the author admits, however, that prefere for one or the other form is to a great extent a mat of habit. The refraction of the macula can only accurately determined in most cases with a dila pupil, and this is specially important in myo where the disc is liable to be tilted and the fun stretched. For the accurate estimation of the ar of astigmatism the use of cylinders in retinoscop far preferable to the refraction of the two meridia spherical lenses alone. Here the author menti a point which is not generally known. W the correct cylinder in the trial frame is at wrong angle the error, shown by the direction which the shadow moves, is greatly exaggerat This enables the surgeon to judge how to shift axis of the cylinder until an equal shadow in meridia is obtained. The ophthalmometer is recommended for accurate work, since it only gi the astigmatism of the anterior corneal surfa Dr. Percival points out that tilting the lens do wards increases the spherical and still more cylindrical power. This device may be of pract value in some cases of high myopia with astigmatis also in prescribing temporary glasses after a catar operation, the immediate effect of which is to ca some astigmatism with the axis horizontal. On subject of periscopic spectacles Dr. Percival n that the anterior convexity of a high plus len often too high. For instance, if a lens of +10D i be made periscopically on a base of −7D, the ante convexity should not be +17D but +16 D, owin the distance from the eye. These and other det are worked out mathematically and the exact figu are given in tables. More than a third of the boo devoted to the application of mathematical optic various practical problems in the prescribing fitting of glasses.

FRACTURE OF THE PELVIS.

Beiträge zur Kenntnis der Beckenbrüche Beckenluxationen. By ANDERS WESTERB Upsala and Stockholm. 1928. Pp. 375.

THIS monograph is Supplement VIII. of LXIII. of the Acta Chirurgica Scandinavica comes from the surgical clinic of the University Upsala under the authority of Prof. Gunnar Nystr The author wrote it in Swedish, and it has b translated into German by Dr. H. Flex. Dr. Wes born, in his preface, states that since the introduc of X rays no thorough study of the subject appeared and that a clinical rontgenological inv gation of the material is required not only as reg the industrial efficiency of the surviving patie but also as to their anatomical recovery and subjec symptoms. The author gives statistics of the ca of fracture in 278 cases as far as ascertainable; of these were falls from a height (including e cases of suicide by jumping out of window), 84 caused by crushes, and the exact mechanism of in was unknown in 34 cases, although mechanic propelled vehicles were concerned in most of th Under the heading of "Fracture of the Pelvis" included injuries ranging from slight to severe, s so severe that recovery is only just possible. Th

re any statistics as to prognosis are valueless unless ey are classified. The gravity of a case depends gely upon the presence or absence of injury to portant structures inside the pelvic cavity. Chief ong these are rupture of the bladder and urethra 0 per cent. of cases). Injury to the kidneys, hough included in these statistics, hardly seems tributable to pelvic fracture. Of 15 cases of rupture the bladder eight recovered. Early operation and rineal drainage in this injury as well as in ruptured ethra is of the greatest importance as a preventive sepsis, which is the most frequent cause of death, art from concomitant injuries. Diagnosis of adder rupture by the injection of sterile air and bsequent X ray photograph is strongly recom-ended. A tied-in catheter does not prevent the currence of sepsis and seems to increase the liability stricture in cases of ruptured urethra.

The general mortality amounted to 12 per cent. all the cases here recorded. Double vertical cture of the pelvic ring was the most fatal (30 r cent.), while fracture of the expanded portion of e ilium was least deadly, having a mortality of ly 3 per cent. 114 pages of the work are taken by small print records of case-histories, illustrated th outlines of X ray pictures. There is a copious bliography and 16 plates of excellent reduced productions of X ray photographs. There is, fortunately, no index.

This is a very painstaking and conscientious dy of the subject.

PHILIS.

Second edition. By HENRY H. HAZEN, A.M., M.D., Professor of Dermatology and Syphilology, Georgetown University and Howard University. London: Henry Kimpton. 1928. Pp. 643. 42*s*.

THE progress in syphilology since the first edition this work appeared in 1919 has necessitated a rough revision, which has been achieved with actically no alteration in size. The earlier chapters ntain useful statistics of syphilis in various sections the American population, as well as a valuable cussion on infection and immunity. Excellent ounts are given of the early stages of the disease. e cutaneous manifestations, which are classified ording to the system of the American Dermatogical Association, are particularly well described l illustrated; a valuable feature is the note the histological changes in each type of lesion. e late lesions are dealt with systematically. The pters on the vascular system and the genito-nary tract are of a high standard and excellent oured plates of the cystoscopic appearance of ical lesions are included. Not many surgeons will port the author's opinion that syphilitic bone ease is a very frequent cause of spontaneous ctures, nor that the clavicle is the favourite bone syphilitic involvement; this last statement is, reover, at variance with the statistics given in the lier part of this chapter. Radiographic evidence a syphilitic lesion has frequently been noted in rcot's joints; Dr. Hazen believes that most nifestations of this condition, especially those of hypertrophic type, are due to the direct action of spirochæte rather than of neuropathic origin. He otes considerable space to involvement of the tral nervous system, drawing special attention the high proportion of cases of early syphilis in ch this system is affected, and to the necessity of mination of the cerebro-spinal fluid. The various es of neurosyphilis in all stages are lucidly described full details are given of the technique and value of Lange gold chloride test. Tryparsamide does not et with his unequivocal approval, but Dr. Hazen is y favourably impressed by the results of intra-nal treatment after the technique of Swift and Ellis, ch is fully discussed. The treatment of general alysis by malarial therapy is dismissed in a very sory manner.

Readers who appreciate the full details of treatment the various stages of the disease given in most modern works of British origin will be disappointed with the chapter on treatment. The sections on the antenatal treatment of infected women, and the treatment of congenital syphilis in infants are certainly not full enough. As to the general principles of treatment, there are evidently differences in practice between England and America. The therapeutic value of bismuth appears to us to be underrated in this book, the author's experience of a high percentage of albuminuria following the administration of this remedy being unusual. Of the organic arsenical compounds, arsphenamine is recommended as giving good results in routine practice; toxic effects with both neo-arsphenamine and sulfarsphenamine appear to be more frequent than with similar preparations of European origin. The simultaneous administration of arsenical compounds and metallic remedies is not recommended.

Throughout the book Dr. Hazen quotes freely from authoritative sources, and gives extensive lists of references at the end of each chapter; he would have done well also to make clear his own opinion, based on personal experience, especially where controversial questions are involved. Students and practitioners will miss this guidance, but will appreciate the impartiality which characterises what is on the whole an excellent work.

DEAFNESS AND ITS ALLEVIATION.

By VINCENT NESFIELD, F.R.C.S., Major I.M.S. (ret.); Ophthalmic Surgeon, Queen's Hospital for Children. London: H. K. Lewis and Co., Ltd. 1928. Pp. 85. 7*s*. 6*d*.

UNDER this title Mr. Nesfield sets out to describe an operation he has designed for the relief of deafness. This consists in gouging away the bone to make a channel 14 mm. in diameter parallel to, and behind, the external auditory canal. The aim in view is to produce an aperture into the middle ear about 5 mm. in diameter. According to the author's description, this "boring" leads into the attic of the middle ear; the mastoid antrum is usually "non-existent, or only present as a thin red line of mucous membrane." The bridge between the "boring" and the external auditory canal is cut away to a depth of about 10 mm., and the external meatus split to make a flap, which is stitched to the under surface of the skin incision. Two tubes, 5 mm. in diameter, are inserted from the meatus backwards into the canal made in the mastoid; these are removed on the next day, and firm plugging inserted and renewed daily for three weeks with the object of keeping the opening patent. Nevertheless, the skin opening nearly always closes over at the back of the external auditory meatus; in time a very thin membrane forms in this situation. Mr. Nesfield claims that the operation improves the hearing in six different ways: (1) by rendering the Eustachian tube patent; (2) by allowing air to enter the middle ear directly through the new opening, "and this appears to be the most potent factor"; (3) sound waves impinge on the membrane which forms over the new opening; (4) the channel not only aerates the middle ear but drains it of mucus; (5) the boring and the increased vascularity resulting in the healing process produce a reflex effect on the cochlea; and (6) the increase of the total space of the middle ear increases the resonance. As to (1) he does not attempt to explain how or why this effect is attained. The benefit claimed in (2) cannot occur when the opening closes over as, on his own showing, it nearly always does; this criticism applies also to (4), while (5) is a highly speculative statement.

The book appeals rather to the general public than to the medical profession; thus, of its 85 pages, but 14 are devoted to a description of the operation, its after-treatment, and its results, while the previous 56 pages contain a popular account of the anatomy and physiology of the ear, and of "the nature of deafness." The author says that, as it is not possible to gauge the result under three years, it is difficult to show exact results. It may be difficult, but it is

surely not impossible, to show the approximate results on all patients operated on three years and more ago. Such tables of the results of treatment have been compiled by other authors of novel methods, and the profession has a right to expect some attempt to show the result in all cases treated by one who makes large claims to alleviate such a disease as chronic deafness.

ACCIDENTS, AND PROBLEMS ARISING THEREFROM.

Lehrbuch der Unfallheilkunde. By Dr. PAUL JOTTKOWITZ, Oberregierangsmedizinabrat, Chief of the Orthopædic Installation, Berlin. Munich: J. F. Lehmann. 1928. Pp. 280 M.15.

THAT this book must cover a great deal of ground is evident when we reflect on the immense variety of injuries that result from accidents. No work quite like it has appeared in this country, where information has to be collected laboriously from text-books on medicine, surgery, orthopædics, and jurisprudence. In Germany, the pioneer country of workmen's insurance, quite a literature has grown up of which this volume is representative. The treatment of injuries is not considered in detail, but their disabling effects are discussed fully, and also the difficult subject of the estimation of wage-earning capacity after crippling injuries or loss of parts. In this last connexion, amputation sites and artificial limbs come under review. The extent of the field will be indicated by the quotation of some of the headings, which range from accident insurance, infected wounds, animal infections such as glanders, tuberculosis, diabetes, acromegaly, and arthritis, artificial limbs. This work is in some sort an epito of medicine and surgery from an industrial insura point of view, the diseases of the special senses be excluded. It is of considerable medico-legal va and certainly should be studied by medical offic concerned with the relations between patients a employers.

DISEASES OF THE BLOOD AND BLOOD-BUILDI ORGANS.

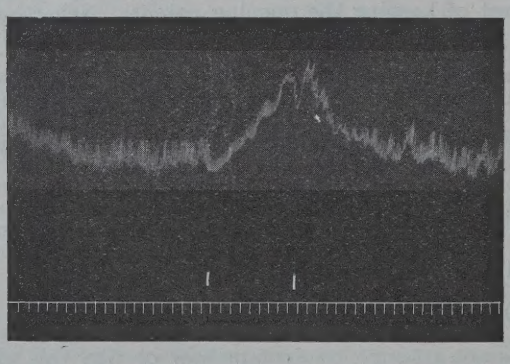
Clinical Pediatrics. Vol. XI. By WILL PALMER LUCAS, M.D., Professor of Pediatrics a ALFRED H. WASHBURN, M.D., Instructor Pediatrics, University of California Medical Sch Supervising Editor, ROYAL STORRS HAYN M.D., Clinical Professor of Diseases of Childr College of Physicians amd Surgeons, New Yo London and New York: D. Appleton and C Ltd, 1928. Pp. 233. 16*s*.

DISEASES of the blood and blood-forming syst form a small but important division of the ills children. In this substantial volume there is padding, and an admirable feature is the inclus of illustrative cases. These are all well chosen a are worthy of close study by those concerned with diseases of children and adults alike. The pe liarities of the blood picture in children, both health and disease, are well described; the secti on the diagnosis and treatment of the various c ditions are satisfactory, but the pathological s might well have been further elaborated.

New Inventions.

APPARATUS FOR RECORDING HUMAN BLOOD PRESSURE.

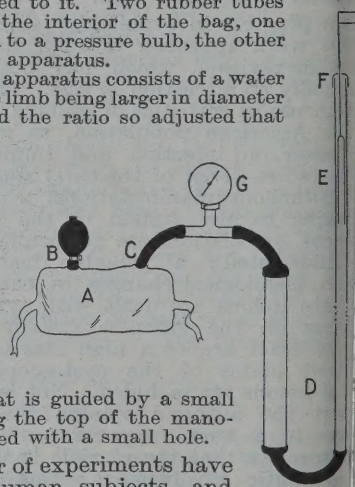
HITHERTO it has been impossible to obtain continuous records of human blood pressure with simple apparatus. Erlanger [1] obtained short continuous records at intervals, but the only apparatus devised for taking continuous records is a complicated apparatus employing an electric valve invented by Kolls in 1920.[2] Moreover, this apparatus did not record rapid variations in blood pressure. Consequently, much important work in relation to variations in blood pressure in human subjects under different conditions either has had to be omitted or has been performed by difficult and unreliable means. The simple apparatus about to be described is a step towards remedying this lack. As will be seen, it is a combination of some well-known apparatus slightly modified, and the instrument is obviously an object for improvement. It consists of two sections.



Continuous human blood-pressure record, showing the effect of respiratory cessation in the inspiratory position. Time intervals 5 secs.

1. An armlet made of a collapsible rubber bag (A), outer surface of one side being made rigid by mean stiff canvas attached to it. Two rubber tubes communicate with the interior of the bag, one (B) being connected to a pressure bulb, the other (C) to the recording apparatus.

2. The recording apparatus consists of a water manometer (D), one limb being larger in diameter than the other, and the ratio so adjusted that one millimetre of mercury difference in actual blood pressure moves the liquid in the recording limb of the manometer an equal distance. To record on smoked paper, a special glass float (E), carrying a light celluloid pointer, is used. The stem of the float is guided by a small glass cap (F) fitting the top of the manometer and perforated with a small hole.



A large number of experiments have been done on human subjects, and the best procedure has been found to be as follows. The armlet is arranged im diately above the elbow, and the subject or lies with the arm supported in a comfort position. The pressure in the bag is raised 20–25 mm. Hg below the subject's systolic pres The requisite tension in the bag to produce pressure can be ascertained by inserting a s meter (G) in a by-tube. In this way, 10-mi continuous records can be obtained without subject experiencing any discomfort. It shoul pointed out that the apparatus does not record sys blood pressure but variations in blood pressure. employing a simple factor the actual blood pres can easily be ascertained if desired. The ten in the bag is, of course, considerably above venous blood pressure and, consequently, vo effects are excluded. A typical tracing obtained this apparatus is shown.

J. H. THOMPSON, B.Sc.,
Demonstrator in Physiology, Department of Physiolo Middlesex Hospital Medical School, W.

THE LANCET.

LONDON: SATURDAY, AUGUST 11, 1928.

HE INTERNATIONAL UNIT OF X RAYS.

AT the First International Congress of Radiology, d in London three years ago, there was a discussion the necessity of establishing an international unit be used as the basis of all X ray measurement of age. It was felt at the time that satisfactory gress in treatment with X rays would not be sible without a unit which could be universally pted. It was therefore resolved that an Inter- ional X Ray Unit Committee be formed, and the tish X Ray Unit Committee, which was established 1923, was requested to communicate with the ysical and radiological societies of the principal ntries throughout the world with a view to the nination of representatives to constitute such an ernational committee. During the last three years British X Ray Unit Committee has had the matter nand and a committee consisting of two representa- es from each of 19 different countries has been med. Each country was invited to submit the nes of two representatives—one a medical man l one a physicist—to serve on this committee. preserve a balance, the British Empire was repre- ted by two members only.

The representatives were invited to submit their ws on the X ray unit and the measurement of age, and it was at once evident from the replies eived that the subject was one in which great erest was taken. A summary of the various points sed was prepared and submitted as a basis for cussion at a meeting of the International X Ray it Committee which met during the Second Inter- ional Congress of Radiology held last week at ckholm. Representatives from the following ntries were present at the meeting: Belgium, cho-Slovakia, Denmark, Great Britain, France, rmany, Italy, Japan, Norway, the United States America, Russia, Spain, Sweden, and Switzerland. is gratifying to know that unanimous agreement s arrived at in the committee meeting concerning main points under discussion. The following ommendations put forward by the International mmittee were unanimously adopted at a general eting of the Congress:—

1. That an international unit of X radiation be pted.

2. That this international unit be the quantity of radiation which, when the secondary electrons are ly utilised and the wall effect of the chamber is ided, produces in 1 c.cm. of atmospheric air a 0° C. and 76 cm. Hg pressure such a degree of ductivity that one electrostatic unit of charge easured at saturation current.

3. That the international unit of X radiation be led the "Rontgen," and that it be designated by letter R.

4. That various standard methods be employed to ablish the unit.

5. That for all comparative purposes it is advisable employ ionisation chambers which have been ibrated in terms of a standard chamber for radiation of the various qualities employed. It is o advisable to make the wall effect of these chambers small as possible.

6. That the practical instrument used to measure X ray output be called a dosage meter.

7. That the constancy of the indications of the dosage meter be tested by means of gamma radiation emitted from a definite quantity of radium element, the measurement being carried out always under the same conditions.

8. That any specification of dosage is incomplete without specifying the quality as well as the quantity of the radiation. The quality of X radiation used for practical purposes is very varied and it would be impracticable to give a complete specification of it; but much information can be obtained from a knowledge of the degree of absorption of the radiation in standard materials, the peak voltage applied to the tube together with the filter employed, and the general character of the high tension apparatus. For practical purposes the quality may be expressed by stating the half value layer in a suitable material or by stating the effective wave-length as determined by the percentage amount of radiation transmitted through a given thickness of a suitable material (copper or aluminium).

In view of the fact that rapid progress is being made in methods of X ray measurement and in our knowledge of X ray phenomena, the Committee felt that the above recommendations should be regarded as provisional. They may be modified later in the light of further information. The adoption of the resolutions marks an important step in the measurement of X ray dosage. Not only will the confusion which has hitherto existed in radiology by the employment of the letter R to denote entirely different quantities be removed, but it will now be possible for a radiologist in one country to reproduce accurately an X ray dose and thus be enabled to compare his results with those of radiologists in other countries. Hitherto this has been impossible since there has been no international agreement concerning the unit in terms of which the dose should be measured. Emphasis has been laid on the need for specifying the quality as well as the quantity of radiation employed in treatment. The recommendations indicate how the quality may be specified, and it would be well in order to obtain as close agreement as possible if radiologists were to employ the methods suggested. The correlation of the physical dose and the biological dose needs careful consideration by the International Committee as it presents many difficulties. Whether these difficulties can be surmounted and a correlation be found is still an open question.

The International X Ray Unit Committee has been authorised to continue its deliberations and to submit a further report for consideration at the next Congress to be held in Paris in 1931. Prof. K. M. G. SIEGBAHN (Upsala) was elected chairman, and Prof. E. A. OWEN (Bangor) and Prof. HERMANN HOLTHUSEN (Hamburg) honorary joint secretaries of the International Committee during the ensuing three years. The British X Ray Unit Committee, which has had the financial support of the Medical Research Council, is to be heartily congratulated on the excellent work it has done during the last three years in preparing the way for the adoption of the resolutions by the Second International Congress of Radiology.

DISSOCIATED JAUNDICE.

SINCE the observations of certain French biochemists called attention to the fact that the elimination of bile-salts and of bile-pigments do not necessarily run a parallel course in certain cases of icterus, the study of so-called dissociated jaundice has been actively pursued by many observers. A recent article by CHABROL,

BÉNARD, and BARIÉTY[1] gives an account of the researches carried out by them during the last nine years on the excretion of bile-salts. The detection of bile-salts is fairly easy, but the quantitative estimation of these bodies either in urine, blood serum, or even in bile itself is a matter of great difficulty. Thus in blood serum these authors have found it impossible to obtain an estimate of the amount of bile-salts present by any method depending on diminution of surface tension. They have, however, been able to apply a modification of Pettenkofer's reaction which will give a positive result in dilutions as great as 1 in 10,000. In the case of urine, Pettenkofer's reaction has also been employed, but here surface-tension estimations have proved of value when carried out by a special technique. It has been found that the NaCl-content of the fluid is of importance, since the concentration of this salt may produce considerable modifications in the results obtained. When duodenal secretions, recovered by means of a duodenal tube, are examined, the estimation of the bile-salts is a simple matter as these bodies are always present in considerable concentration. The French observers have found that methods of estimating surface tension are the most readily applicable in this medium and give results of great utility, even if no claim to fine exactitude can be made. The principal conclusions drawn from their observations are as follows :—

(1) In normal circumstances, bile-salts can never be found except in the first part of the small intestine, the duodenal fluid giving figures in the neighbourhood of 15 g. per litre. The authors have given the name of biliary index to the ratio salts/pigments, and find that this index is normally in the region of 40. In the blood serum they are able to assert that if bile-salts are ever present in physiological conditions their concentration is certainly below 0·1 g. per litre, and as regards the urine they are again unable to find any evidence of the presence of these bodies normally.

(2) In the case of hæmolytic jaundice, the findings are comparable to those in the normal—i.e., bile-salts cannot be found in the blood serum and they do not lower the surface tension of urine. Duodenal tubage, on the other hand, gives a ready demonstration of the dissociation which is held to be present in jaundice due to excessive hæmolysis, the biliary index in such cases being as low as 6 instead of the normal 40.

(3) In obstructive jaundice bile-salts should theoretically be found with the greatest facility. Some 10–15 g. of bile-salts are normally excreted daily in the bile, and in cases of grave obstruction to the biliary passage it would be expected that a large part of this would appear in the urine, but such does not appear to be the case. In a series of 15 cases of grave obstructive jaundice, the authors have been surprised to find in the blood serum only the smallest trace of the bile-salts in spite of the presence of a high concentration of bile-pigments in the blood. In reality, the proportion of bile-salts was ten times less than that of pigments, whereas in normal bile these proportions are reversed. The first possible explanation of this fact is that the renal threshold for bile-salts is much lower than that for bilirubin. The study of the urine in such cases does not support this thesis, for whenever the concentration of bile-salts in the urine is measured, it is found that the amount eliminated in obstructive jaundice is relatively small, and there have often been cases of obstructive jaundice in which the pigmentation was of the deepest degree, and yet the urine showed an almost complete absence of bile-salts.

The conclusion is drawn that any icterus which goes on for a long time tends to be accompanied with a disassociation of the amount of bile constituents excreted, the pigments being the elements showing extreme retention. According to the theory of LEMIERRE and BRULÉ, such a condition, in wh Hayes's reaction is negative, in spite of an inte choluria, indicates dysfunction of the hepatic cells, following CHABROL, BÉNARD, and BARIÉTY, the t explanation would appear to be that there is a gen deficiency of bile-salts in the organism in these ca and they base this belief on the fact that the small qu tities of bile which can be recovered by duodenal tub in such circumstances demonstrate a considera diminution in the relative content of bile-salts. explain such a disappearance of bile-salts from bile itself they have recourse to the fact that ch sterol is noticeably increased in the blood in all th circumstances, and they hold that it is possible t this increase of blood cholesterol is in part due t failure of the liver to form bile-salts. Apart from t the fact that the normal circulation of bile-salts fr the liver to the intestine and then back by the po vein to the liver has been interrupted by the prese of an obstruction, is thought to be sufficient to br about a steady diminution in the bodily reserve bile-salts.

In conclusion, these authors have attempted discover whether there are not frequently variation the excretion of bile-salts amongst patients suffe from diseases unaccompanied by jaundice. Here, ag caution must be observed because the surface ten of urine can be materially affected by many bo in addition to bile-salts—chlorides, albumin, polypeptides being outstanding examples. In m cases of secondary carcinoma of the liver, and du the course of certain acute infections, observation the surface tension, together with a modified Pet kofer's reaction, point to the possibility of an exces excretion of bile-salts. These findings must, howe be accepted with reserve. Still more interesting certain observations on the effect of injecting an ex of bile-salts into the blood, it being found that intravenous injection a concentration much hi than that ever observed during biliary obstruc can be produced without any accompanying pru or bradycardia.

ACTIONS AGAINST GOVERNMENT DEPARTMENTS.

GOVERNMENT departments are far from enjoyi good press at the moment. Judges abuse the well-reported phrases; Prof. J. H. MORGAN has attacking them in two articles in a popular eve newspaper; the Lord Chief Justice is understoo be devoting the Long Vacation to preparing publication a book in criticism of bureaucr Though it is not unknown at public dinners for civil service to hear itself praised for its compet integrity, and self-effacement, there are plent cases (especially during war time) where Governm departments have deserved the condemnation have received. In one sense bureaucracy is increa and must increase. The manifold activities of Home Office and the Ministry of Health—in directions as the inspection of factories, the not tion of diseases, and the general supervision of h services—are in a measure an infringement of pers liberty. But it is too late to say that Governm departments are not to interfere in these mat On the other hand, the departmental attitude easily exceed what is reasonable, especially in absence of legal check. The medical profession not be specially concerned, but it remember difficulties when panel doctors found the Minist Health exercising not only executive but also ju

nctions and seeking to bar the avenue of appeal to e law courts. As a member of the public, too, the actitioner may be surprised at the results of the ctrine that the King can do no wrong. A doctor's otor-car may be smashed by a negligently driven my lorry and the only remedy may be a futile im against the corporal at the steering-wheel. , if a postman steals a registered and insured postal cket, it may turn out that the compensation is rely discretionary not contractual. It is not important, therefore, to inquire the nature of the gal liability of State departments and to consider ssible reforms.

Mr. J. W. GORDON, K.C., has recently published a mphlet on "The Crown and the Courts" (Stevens,), setting out the case for reform illustrated by stances and judicial comments. His examples of e sins of Government departments are set out under veral heads such as "usurpation of authority," respass to property," "imposition of unauthorised xation," and "delay or denial of justice"—damning list which suggests that the time has me for a fresh Magna Charta. The difficulty is at esent that the Crown is immune from liability for e wrongful acts of its servants. Petition of Right ll not lie for what the lawyers call a tort. There is me doubt whether this rule is historically well unded, but it is solidly established to-day and thing but a new statute could upset it. In at least e of our self-governing Dominions the rule does not ist. Under an Act of 1903 the Commonwealth of stralia can be made responsible for the actions of officers just as a master can be made liable for e actions of his servants. Australia has abolished e complicated and anachronistic procedure by way Petition of Right and has put the subject when ing the Crown in no worse position than if he were ng another subject. Something of the kind is quired in England. The obsolete procedure and the e-sided prerogative ought to be modernised and odified. After the war a strong committee was pointed by Lord BIRKENHEAD, when Lord ancellor, to consider the position of the Crown as gant and to prepare a Bill to amend the law as nd desirable. After long delay, as Mr. GORDON rs, a Bill was produced more than a year ago t nothing more has been heard of it. It may be ged that the matter is complicated and not free m controversy. The departments naturally fear a ltitude of petty claims—for example, if the miralty carries out big gun firing near the coast d windows are broken. Nevertheless, it is understood that most of the Government departments are pared to accept the Bill. Little will be done unless blic opinion applies pressure. Mr. GORDON'S mphlet is therefore timely, and those who wish to rsue the matter beyond the mere collecting of thologies of judicial abuse of Government departments should study the draft Bill which was published Cmd. 2842 in April, 1927.

AN International Conference on Light will be d at Lausanne and Leysin from Sept. 10th to 13th next. ose taking part will include Prof. H. C. Dorno (Davos), f. C. Fabry (Paris), Prof. V. Henri and Prof. Bloch rich), Dr. Leonard Hill (London), Prof. Hausmann enna), Dr. Alfred Hess (New York), Prof. Axel Reyn penhagen), and Dr. A. Rollier (Leysin). Among the jects to be discussed are the methods of measuring the rgy and biological activity of light rays, irradiated foods l sterols, the climatic and light therapy of various forms uberculosis. Dr. G. Murray Levick is acting as general norary secretary of the Conference in England, but all rance fees and general inquiries should be addesssed to Secrétariat-général de la Première Conferénce Internationale de la Lumière, Lausanne, Switzerland.

Annotations.

"Ne quid nimis."

THE DIAGNOSIS OF TUBERCLE IN GENERAL PRACTICE.

THE diagnosis of consumption presented no difficulty to the practitioner of 50 years ago. If cough, blood-spitting, wasting, night-sweats, and hectic flush proclaimed the disease the patient's friends were advised that he was in a state of consumptive decline, and the verdict was received as a sentence of death. The customary precautions were taken to postpone, as far as might be, the inevitable end. The dangers of fresh air were met by closed windows whose crevices were further sealed by crimson covered bolsters filled with sand. The bed was screened by heavy curtains, scarcely withdrawn to permit access to the sufferer. The patient's resistance was supported by drugs liberally prescribed, and blood-letting was resorted to in extremity. When the end came, both doctor and relatives had the satisfaction of knowing that everything possible had been done, and bowed themselves before the mysterious dispensations of Providence.

We know to-day that the symptoms and signs on which the doctors of a previous generation relied for diagnosis represent the last stages of disease and indicate as certainly as in the days of the younger Dumas the near approach of death. The importance of diagnosis at a much earlier stage as offering the only hope of cure has been emphasised by every teacher since the day when Koch made his great discovery. Indeed an almost morbid care has been exercised in the attempt to discover the earliest possible signs of tuberculosis. Great importance has been attached to almost imperceptible variations in breath sounds, and the skill of a piano-tuner demanded to determine relative changes in the percussion note of the lung apices. In recent years thousands of persons have been stigmatised as tuberculous and admitted to sanatoriums, where they have received treatment for non-existent disease, and been saved from a peril that never threatened. A more rational appreciation of the nature of tuberculosis, and in particular of the distinction between infection and disease, has led to a more reasonable attitude on the part of those specially interested in the care of the tuberculous. But the general practitioner, mindful of the teachings of his student days, and aware of some change in the modern attitude, remains in doubt as to the course he should pursue when confronted by a doubtful case. Any lack of acuity on his part may deprive his patient of the only chance of cure, while overscrupulous care may awake groundless fears and pave the way to chronic invalidity. A false step on his part may not only involve a period of needless inactivity for his patient, it may be responsible for either of those twin obsessions, the dread of the phthisophobic or the craving of the phthisophilic. The latter condition is perhaps more common than the former.

Dr. Lawrason Brown, of Saranac Lake, has endeavoured[1] to clear the air by setting up a diagnostic standard representing the minimal requirements for diagnosis. If he has erred it is on the side of boldness, but he has undoubtedly turned the hose of common sense on the sacrificial fires of the phthisical expert, and the practitioner whose hand may have lost some of its cunning and whose ears are slightly dulled by the passage of time will be grateful to him. His diagnostic criteria are: (1) hæmoptysis of a drachm or more; (2) pleurisy with effusion; (3) moderately coarse râles above the third rib and the third vertebral spine; (4) a parenchymatous Rontgen ray lesion in the same area; and (5) tubercle bacilli in the

[1] Jour. Amer. Med. Assoc., 1928, xc., 1032.

sputum. He claims that careful attention to these points will enable a correct diagnosis to be made in about 98 per cent. of all doubtful cases. Taking Dr. Brown's criteria seriatim—

(1) It will be noted that for significant hæmoptysis Dr. Brown postulates an amount of blood of not less than a teaspoonful. He thus excludes those cases of "coloured" or "streaky" spit which, except in cases of chronic fibroid phthisis, are usually due to causes other than tubercle. We might add that a hæmoptysis which the patient delights to describe is seldom tuberculous in origin, while one which he strives to minimise or attribute to epistaxis is almost invariably of sinister import.

(2) Pleurisy with effusion should obviously be treated as tuberculous unless some other cause is manifest, while dry pleurisy should at least be regarded as a danger signal.

(3) The significance of râles is usually appreciated, but the old and incorrect teaching that tubercle usually commences in the lung apex may lead to error. The signs of the graver types of phthisis, especially in the young, are usually found below the clavicle. The true apex of the lung is more often the site of abortive disease. A careful examination of the axillary regions may reveal crepitations when the upper half of the lung, both anteriorly and posteriorly, is apparently free. The necessity of auscultation over the lateral walls of the chest is too frequently forgotten.

(5) The importance of repeated examinations of the sputum for tubercle bacilli cannot be exaggerated. The failure to apply this simple test is responsible for more errors in diagnosis than all other causes put together. If five examinations at weekly intervals yield a negative result, the practitioner may regard the future of his patient with some degree of equanimity. There are exceptions to every rule, and all the circumstances of the case must be taken into account, but the records of any dispensary will show that, provided a conscientious search for tubercle bacilli has failed to discover the bacillus in the first instance, only in rare cases will a positive finding be forthcoming at a later date. Especially where young adults are concerned, experience does not support the statement frequently made that the "T.B. minus" case, failing sanatorium treatment, will later develop into a "T.B. plus" case.

(4) X rays are invaluable in the differential diagnosis of chest diseases, but a poor skiagram is worse than useless. Unless, therefore, a first-class apparatus and a skilled interpreter are available, the general practitioner will be compelled to rely on the symptoms, physical signs, and bacteriological tests. A history of exposure to infection obviously indicates the need for special care, but whenever possible a radiographic examination of the chest should be made, for, as Dr. Brown rightly insists, it is only in the absence of each of the five criteria that pulmonary tuberculosis can be excluded with confidence.

THE STYPTIC EFFECT OF TRANSFUSED BLOOD.

IT is generally agreed that blood transfusion is the most effective means of combating bleeding which occurs as a manifestation of the "hæmorrhagic diathesis." That this transfusion should have a beneficial effect by replacing lost blood is obvious, but it is far from clear why it should also stop the hæmorrhage, either for a time or permanently. The assumption has been that its hæmostatic effect is due to the introduction of thrombocytes or platelets into the circulation of the bleeder, but in considering this it has to be remembered that although most patients with manifestations of the hæmorrhagic diathesis show a thrombopenia, they do not all do so. Many a case has been reported in which bleeding ceased without any increase in the number of the platelets, and there are even records of hæmorrhage persisting despite the presence of platelets in fair numbers in the circulating blood. Evidence against the supposed hæmostatic activity of the transfused platelets brought forward by Dr. Heinrich Engel,[1] of Prag as a result of observations made in the course treating four thrombopenic patients by blood tra fusion. He found each time that within a hours of transfusion the platelet count of the recipi had fallen to its original low level. In one observations were made during and for 24 hours a the transfusion. In the course of the transfusion blood was found to contain 28,110 platelets per c.m within one hour they had fallen to 10,460; wit six hours to 375, and 24 hours later to 80. E concludes that the beneficial results of blood tra fusion in the hæmorrhagic diathesis are due prima to the replacement of blood, which gives the pat a chance to tide over the thrombocytopenic peri he further believes that the transfused blood exerc a styptic effect which, although not due to the in platelets it contains, may be partly traceable to t disintegration products. A part of the styptic eff he suggests, may be in the nature of a protein sh reaction, due to the parenteral administration foreign protein, and in view of the well-known that the coagulability of the blood is increased a the induction of anaphylactic or anaphylactoid st this suggestion appears reasonable. It is suppor by the common observation that those transfusi followed by pyrexia and even a definite rigor particularly effective in stopping hæmorrhage. Si such reactions occur most frequently after transfu by the citrate method, this may perhaps be regar as recommending the method when arrest of hæm rhage is desired.

GALL-BLADDER DISEASE IN THE YOUNG

Dr. A. H. Potter[2] maintains that contrary to generally accepted opinion, infections of the g bladder occur most commonly in adults under mi age, and that they may be met with quite ofte adolescents and young children. In support of contention he states that statistics of about 25 cases of gall-bladder disease collected from reports of well-known clinics and hospitals show the average age of patients at the time of opera is 36 years for females and 39 years for males, interval between the onset of symptoms and time of operation varying from 3 hours to 39 y As regards the incidence of gall-bladder diseas very young persons Dr. Potter has collected tabulated 226 cases in children not above 15 y of age, beginning with Gibson's case, reported in 1 and ending with August, 1927. Negroes appea be far less frequently affected than members of white race. It is noteworthy that while in n instances the symptoms in children were as ty as in adults, children are rather inclined to com of abdominal pain when gall-bladder diseas present. Dr. Potter contends that the acute i tious diseases of childhood have not received attention they deserve as factors in the evolutic gall-bladder affections. Whereas in the past typ fever was generally the preceding factor in bladder disease, of late years there has been a g decline in the incidence of typhoid, and if this tinues the disease will be practically eliminated. the other hand, there has been a great increas influenza which Dr. Potter thinks is taking the of typhoid as a factor in gall-bladder disease. A infections of the gall-bladder and cystic duct usually accompanied by hydrops, which may transitory or permanent. As the inflammation sides the cystic duct recovers its function, drai of the gall-bladder takes place, and hydrops appears. Four cases in Dr. Potter's own pra occurred in a boy, aged 11, who had had influ the previous year; a boy, aged 6, who had had sc fever 18 months before; a girl, aged 15, who had influenza in the previous year; and a girl, age without any history of illness. This incidenc

[1] Med. Klin., 1928, xxvi., 888.

ectious disease seems hardly greater than might be pected in a random sample of the child population. l the cases made a good recovery without operation.

ETHYLENE IN THE OPERATING THEATRE.

ETHYLENE for general anæsthesia has not in this untry received the welcome with which it apparently ntinues to be greeted in America, and in the most ent contributions to the subject[1] we find nothing to ke our views more favourable towards its use. e writers, having claimed ethylene as "one of our st general anæsthetics"—which for short operations may grant them as a correct description—proceed discuss the explosibility of the gas. In saying at this should not be ignored, they find that ethylene liffers very little from ether in this respect," but er demonstrate how great the difference actually by detailing the precautions that should be observed avoid explosion during the use of ethylene. Although se precautions are described as "not burdensome," y appear to outweigh any of the advantages monstrated for the use of ethylene. The system for oiding danger "available at little expense and uble" involves insulated copper wire running along gas tubes, metallic paint for covering the rubber gs (which must each contain about a pint of water), d a moist cloth attached to the metal frame at e back of the apparatus. "Any potential set up the gas escaping under high tension through the lucing valves or by friction in the rubber tubes is once grounded before the mixing of the ethylene d oxygen." The outside of the rubber tube is ated with the metallic paint. Within the tube is bare spiral copper wire soldered to metal at each d. "It has also seemed advisable to solder a conxion to the metallic spiral in the wall of the rubber be." Before each operation water is run through e tube. The anæsthetist's feet rest on a moist th, or he sits on a stool attached to a moist th. A special system of grounding must be worked t based on the fact that cement and tile are good nductors, but wood, linoleum, and rubber-covered ors are poor conductors. After studying the ecautions required for the safe administration of ylene according to these authors, we are left in ubt whether the anæsthetist should be best qualified a fireman, an architect, or an electrical engineer.

UBLIC HEALTH CONGRESS AND EXHIBITION.

A CONGRESS will be held at the Royal Agricultural ll, London, during the week Nov. 19th to 24th, der the auspices of the various British municipal sociations interested in public health administration. e congress will be formally opened on the Monday th an address by the Minister of Health, and on the ernoon of the same day Sir George Newman will eak on the purpose of the public health services. Tuesday morning Sir Walter Fletcher will deal th research in relation to public health, and in the ernoon Dr. C. H. Bond with local organisation for e prevention and treatment of mental disorders. using and milk-supply will occupy the attention the congress on Wednesday, the introducers being . E. D. Simon and Mr. Wilfred Buckley. Thursday ll be given up to water-supply and sewage, the incipal speakers being Prof. W. J. Wilson, of Belfast, . J. H. Coste, chief chemist to the London County uncil, and Mr. John Gardner, of the West Riding vers Board. On Friday morning the new medical icer of health for the city of London, Dr. W. M. illoughby, will speak on food protection, to be llowed in the afternoon by Mr. R. H. P. Orde on e construction and equipment of hospitals. The al day of the congress will be given up to the bject of town cleansing. Official delegates to the mber of many hundreds have been appointed, and eir expenses will be paid by their local sanitary authorities. In the congress hall an exhibition will be held throughout the week, conducted on lines similar to that of the Public Works, Roads and Transport exhibit organised for many years past by Messrs. May and Pattisson, of 13, Victoria-street, London, S.W. 1.

FOOT-AND-MOUTH DISEASE.

FOOT-AND-MOUTH disease is of special interest to the pathologist, as its virus readily passes the pores of a fine porcelain filter, and the susceptibility of the guinea-pig to its action makes the disease a favourable subject for experimental research. The report [1] which has just appeared deals almost exclusively with the disease in small laboratory animals. Improved accommodation for large farm animals has, however, now been completed, and the experimental results obtained with guinea-pigs can be further tested on cattle, sheep, and pigs. The work on which the report is based (set out in three appendices) has been carried out at the Laboratory of the Ministry of Agriculture by Dr. F. C. Minett, at the Lister Institute by Dr. H. B. Maitland, Dr. T. Hare, Mrs. Y. M. Burbury, and Mrs. M. C. Maitland, and at the National Institute for Medical Research by Mr. J. A. Galloway and Dr. S. Nicolau. Mention is also made of research undertaken at the Lister Institute by Prof. A. Ciuca, of Bucharest. A fourth appendix contains a bibliography of work published since the last report appeared. An introduction contains brief reference to important recent work in other countries.

Lebailly and Vallée have noted the early appearance and rapid decline of infectivity in this disease in cattle, and the report contains evidence that active virus cannot as a rule be detected in the lesions of guinea-pigs beyond the third or fourth day after inoculation, though it was found by Dr. Hare in the apparently healthy skin of the ears as late as the tenth day. The results are similar to those obtained by Reppin who could not recover virus from the mouth in cattle later than the eleventh day after infection. Such observations contrast with the prolonged infectivity of the skin and mouth lesions and of the bone-marrow in the dead body, which have been shown to retain active virus for several weeks or even months if the animal has been killed during the infective period and the carcass kept at a low temperature. The viability of the virus on inanimate objects has been further investigated, and survival in vesicle fluid dried on glass and kept in a desiccator at 18° C. for at least two years is recorded. When dried on bran and kept under more natural conditions in the open air of the laboratory the virus has been found active after 40 weeks. Existing evidence therefore points to fomites rather than carriers as the reservoir of infection. Dr. Minett has tested the disinfectant action of a large number of substances, and finds that both acids and alkalis when highly diluted are very destructive to the pure virus; in the presence of organic matter they are much less effective. A 1 : 1000 solution of formalin sprayed on hay was capable of disinfecting it without making it unpalatable as fodder. Mrs. Burbury found that a temperature between 50° and 60° C. rendered inactive the virus contained in liquids, and that an orderly relation existed between temperature, time, and the concentration of the virus similar to that found in the case of bacterial emulsions. The duration and degree of immunity of the guinea-pig and the factors responsible have been examined, and a fairly close relation between the content of antibodies in the blood and the degree of resistance of the animal has been found to exist. It was recorded in an earlier report that a certain degree of active immunity resulted from inoculation with a vaccine consisting of virus killed with formalin. The effect of such a vaccine on the resistance of guinea-pigs has been studied, and confirmation of the previous results has been obtained.

[1] Ministry of Agriculture and Fisheries. Third Progress Report of the Foot-and-Mouth Disease Research Committee. Pp. 141. H.M. Stationery Office. 1928. 5*s*.

It has not, however, been possible yet to test the method on cattle in this country. Vallée, however, has reported encouraging prophylactic results in bovines with a formalised vaccine. The differences existing between the three types of virus found in Germany by Waldmann and Trautwein have been confirmed, but, with one exception, the type found in Great Britain has always belonged to the same type as Vallée's O strain. Three methods have been successfully used for determining the type of a virus :—

1. Inoculation of animals recovered from an attack due to virus of a known type.
2. Inoculation of animals protected by a formalised vaccine made with a known type.
3. Inoculation of animals passively immunised with serum of a known type.

Prof. Ciuca, using materials from guinea-pigs, has found complement fixation an effective method of demonstrating the presence of antibodies in the serum of recovered animals and of determining the type of virus present. Further experiments with rats and rabbits have confirmed previous observations showing the slight susceptibility of these animals, and have given no support to the suggestion that the disease is spread by rodents. Mr. Galloway and Dr. Nicolau give an illustrated account of the minute structure of the secondary vesicles on the tongue of guinea-pigs following inoculation of the virus into the sole of the foot. The work was needed because former studies had almost entirely been concerned with lesions at the site of inoculation or with vesicles in a comparatively late stage of the natural disease. The earliest pathological changes detected were small groups of three or four epithelial cells situated at varying depths between the stratum granulosum and the basal layer. The cytoplasm of these cells showed an altered staining reaction, and the nuclear chromatin was condensed into one or more deeply staining masses. At the same time, or very soon after, two or three polymorph leucocytes appeared close to the altered epithelium, but no cellular reaction in the corium could be detected at this early stage. The histological evidence thus brought forward favours the view held by Galloway and Nicolau that the multiplication of the virus is primarily in the epithelial cells. Mrs. Maitland has found that after inoculation of the sole of one hind foot the usual secondary vesicles could be prevented from appearing on the other foot by protecting the latter from pressure with a splint or a cotton-wool pad. On the other hand, if parts of the feet and toes not usually affected were subjected to increased pressure, vesicles appeared on these unwonted sites. Not only was the formation of vesicles controlled in this way, but experimental examination of the skin of the feet showed that the virus had not multiplied in the usual way at the sites of predilection on the soles when vesicles did not occur. The fact that the coöperation of the virus and pressure was needed to produce both the ordinary lesions of the generalised disease and free propagation of the virus in the usual sites is an interesting example of mutual action and reaction of an infective agent and the tissues.

The report shows steady progress in our knowledge of the infective agent, the pathology, and the nature and control of immunity in this important disease.

PROTECTION OF MOTHERHOOD IN SWITZERLAND.

EIGHTEEN years ago Dr. Bernheim Karrer stated in writing that there was nothing which could fairly be described as systematic protection of motherhood and infancy in Switzerland. A good deal of progress has been made in the meantime, and in a recent issue of the monthly bulletin of the International Office of Public Health Dr. Karrer, who is now director of the cantonal day nursery at Zürich, gives a critical survey of the work undertaken for the preservation of maternal and infant life. He still finds his country behindhand in the matter of antenatal supervision, stating that German-speaking Switzerland possesses no such thing as an ante clinic except for one or two connected with mate hospitals. In French-speaking Switzerland ante clinics are distinct institutions, but there are few of them compared with the number of welfare consultations. Again, while laws are in which make careful provision for the nursing mo both in money grants and exemption from h work, the pregnant woman may ask to be exc from work in a factory for eight weeks before con ment only at her own expense, there being no fina help to enable her to do so. This poverty of ante care is the more unfortunate, since little impr ment has been effected in the toll of stillbirths deaths in the first four days of life during the 15 years. Whereas the general infantile mort stands at 56·5, comparing favourably with many European countries, the mortality of the first days is 19·2. In other respects, however, st have been made; pædiatrics is now an obliga subject in the medical course and examinations, the study includes hygiene and feeding of infa Midwives, who are still the chief counsellors of S mothers, have also had their training stiffened up lengthened, and health visitors and baby nurses a year's course followed by examination. Instruc of the public, and especially of mothers, is forwa by schools for mothers, infant consultations (al conducted by doctors), and travelling exhibit The institutions for the care of babies include mate hospitals, children's hospitals with wards for infa refuges for mother and child together, baby shel day nurseries, and residential nurseries. The nu at Zürich, of which Dr. Karrer has charge, is a h with 45 beds, attached to the obstetric clinic; primarily intended for premature infants, but admits sick newly-born infants referred from the cl Many children are put out to nurse and, th nominally under medical supervision, in some dist the supervision is by no means satisfactory. In Zü the work is carried out from a child protection o and is so well done that Dr. Karrer suffers less an on behalf of illegitimate infants who leave the nu than of those whose parents are poor and improvid A number of similar voluntary societies, as we the national organisation " Pro Juventute," do u work in backing up the State provisions.

ATMOSPHERIC POLLUTION.

THE thirteenth report of the Advisory Committe Atmospheric Pollution[1] covers observations mad the year ended March 31st, 1927. It is the las these reports to be issued from the Meteorolo Office (Air Ministry), for the work has been transfe to the Department of Scientific and Indus Research which will from now on coördinate records and prepare an annual report thereon. task will remain in the hands of Dr. J. S. Owens, can be addressed at 47, Victoria-street, Lon S.W. 1. In addition to this routine survey sp researches are to be directed towards the solutio the scientific problems of atmospheric pollution, these will come under the Director of Fuel Rese supervised by a committee of the Department which Dr. G. C. Simpson, F.R.S., is chairman, Mr. J. K. Best (Cadbury Bros.), Mr. J. H. Coste (Chemist, L.C.C.), Dr. G. M. B. Dobson, F. (Lecturer in Meteorology, Oxford University), R. Whytlaw-Gray (Professor of Chemistry, L University), and Sir Napier Shaw are mem The last named has also expressed his willingne serve as the first chairman of a standing conferen coöperating bodies which will continue the cons tive work of the Advisory Committee. The re as heretofore, contains a mass of information on deposit of impurity at 80 different stations in United Kingdom. Although the good stations tinue to show improvement the bad ones remai

[1] Department of Scientific and Industrial Research. Investigation of Atmospheric Pollution. Thirteenth Re H.M. Stationery Office. 1928. Pp. 54. 6s. 6d.

l as ever. The highest deposit of tar as well as of phates was at Burnley; the lowest in either category Southport (Hesketh Park). Newcastle-on-Tyne red highest for carbonaceous or sooty matter ich there may make up 40 per cent. or more of the al deposit, the lowest record being at Rothamsted. ne of the reduction in the deposit of sulphates ms to be due to the increasing use of gas as a fuel. London and Glasgow from 1914 to 1927 the sulphate posit has diminished out of proportion to the total. interesting curve shows the effect of suspended oky matter in the coal stoppage of 1926 at Stoke-on- nt; in London the event produced no appreciable ct. It is also clearly brought out in a curve that rly the whole of the ultra-violet rays of sunlight cut off by a comparatively small amount of smoke the air. An interesting account is given of a haze Norfolk which was found to consist of salt crystals. ile the continuance of these detailed observations der the ægis of the Research Department is assured, must be no small satisfaction to those who have en a share in this laborious survey for so many rs that there will now be fitting opportunity for anised research into the scientific problems olved. The time is ripe for drawing conclusions m an immense wealth of material.

SYNTHALIN IN DIABETES.

THE use of insulin in diabetes has certain disadvantes. Although the necessity for injection encourages ct dosage, so far as quantity is concerned, it does reproduce the conditions of physiological secretion, where large doses are given the immediate ult of its administration may be an excessive luction of the blood-sugar, followed later by hyperæmia when absorption of carbohydrate from the estine is well under weigh. From almost every int of view it would be preferable to use a drug ich could be given by mouth and absorbed slowly h other contents of the alimentary canal, and high pes were raised a couple of years ago when it was ggested that insulin might find a supplanter in the w German preparation called synthalin. This drug d not been invented ad hoc, but had been evolved ring a series of investigations on parathyroid any in which it was found that guanidine caused all in blood-sugar. This happened only at the cost poisoning the animal, but aminobutyleneguanidine ved less toxic, and synthalin—so far the most isfactory of this series of substitution products—s recommended as relatively innocuous.

Synthalin contains two molecules of guanidine, ned by ten CH_2 groups, and its action is shown to be olly different from that of insulin, as it lacks the ential power of promoting the oxidation of glucose. e first accounts of its effect on patients were neverthes distinctly favourable. Frank, Nothmann, and agner[1] reported that sugar disappeared from the ne in mild cases of diabetes and that the blood-gar was lowered, though not reduced to normal; severe cases the dose of insulin could be reduced. ey admitted that synthalin did not act quickly ough to benefit patients in coma, and they did not prove its use for children. The Medical Research uncil arranged for tests in this country, and preinary reports from many British hospitals were blished in THE LANCET about a year ago.[2] These luded investigations carried out at St. Bartholew's by Dr. George Graham and Dr. G. C. Linden, o have now published a more detailed account of eir work.[3] In 8 patients out of 12 they found that nthalin caused a very definite and apparently neficial change in the carbohydrate metabolism. one of the eight 50 mg. of the compound replaced -45 units of insulin without the blood-sugar exceedg the normal limit, but in the remaining four it orded no practical benefit. These results are not so good as those of the early workers, but they are better than some of the others reported. The mode of action, as Graham and Linden point out, is still obscure. Insulin is a natural secretion, and will always lower the blood-sugar if enough is given; synthalin is a foreign chemical and has no action on sugar in vitro. They consider that synthalin must influence the carbohydrate metabolism by modifying cellular activity, and that this action is possibly a minor part of the more general effect that shows itself in toxic symptoms. It may work by depressing the power of the liver (increased in diabetes) to deaminise amino-acids, or its action may be regarded as a slight degree of a poisoning which when severe causes nausea, vomiting, pain, and jaundice. It is, of course, possible that its effect on carbohydrate metabolism is distinct from its toxic action, and that its failures are due to some idiosyncrasy in the patient. If this is so, it offers a parallel to salvarsan, which does not itself kill spirochætes, but causes the body to generate a lethal substance, and which also fails in some patients, whilst on occasion it produces effects comparable with those of synthalin. The toxic properties of synthalin are, however, a very severe drawback to its employment, for few patients who have experienced them will ever run the risk again. They occurred in 5 out of the 12 cases treated in this test. As prophylaxis against them, Frank has recommended that the dose of synthalin be withheld every fourth day, and A. Adler uses with each dose grs. 3 of sodium dehydrocholate ("decholin") which increases biliary secretion and may perhaps accelerate the excretion of synthalin from the liver.[4] This preparation was not tested at St. Bartholomew's Hospital, but Graham and Linden suggest that it should always be used, and that the dose should be carefully limited by starting with small amounts and gradually increasing them.

The fate of the sugar which disappears is unknown. It is not found in the liver or muscles as glycogen, and the lactic acid which is formed quickly vanishes again. Synthalin may merely destroy the sugar in the blood as yeast does in the stomach, but the appearance in one patient of a severe ketosis three days after the suspension of treatment suggests that the disappearing sugar was at least exerting an anti-ketogenic influence. To sum up, Graham and Linden say that there is no good evidence that the patients are really the better for having synthalin. Patients who need insulin had better use the natural product if possible; the new synthetic rival has a place only when there is a reason against injection.

HARVEST BUGS.

WE have in this country so few animals which bite and prick and sting with serious results that we make a good deal of fuss about beasts which are hardly worse than interesting. And now that the season of sitting about in the open air is with us, many people who respond vigorously to its attentions will lament the existence of the harvest bug or mite. They should also read the account of the animal and its allies which is given by Mr. Cecil Warburton in *Parasitology* (July, 1928, p. 228). There are about a dozen species of mites which afflict man in much the same way in different parts of the world; in all cases it is the larva alone which is parasitic and, as the adults are hardly known, the systematics of the subject are considerably muddled. The only one of which the life-history may fairly be said to be known is the Japanese *Trombicula akamushi*, which is something more than an annoyance because it transmits the river fever or tsutsugamushi disease. The larva in this instance is found abundantly on field mice and readily attacks dogs, cats, guinea-pigs, and other animals besides man. After much labour Miyajima succeeded in rearing adults and found that they were neither parasitic nor predaceous but can be reared on such food as potatoes and melons and appear

[4] Klin. Woch., 1927, vi., i., 493.

in nature to live on various plants; moisture is essential. Our national harvest bug is also a larva; none of the few people who have tried has succeeded in rearing the adult form, so that we have no means of knowing where and how it lives. More extraordinary still, perhaps, is the fact that those who study wild mites have failed to find one which may reasonably be supposed to be the missing parent. Obviously there is room here for an interesting piece of work. Dry grassy places, chalk downs, and the like, seem to be the animal's favourite habitat; it evidently lives somewhere, possibly underground or in the nests of mice. Meanwhile the best treatment for those who are particularly susceptible seems to be a complete change of clothes and a bath.

SCARLET FEVER ANTITOXIN.

WHEN this antitoxin was first introduced the important question was whether we had, or had not, found a useful agent in the treatment of scarlet fever. That question has been answered in the affirmative. Though no efficient serum appears to be yet available for combating the septic complications such as adenitis, otitis, or mastoiditis, there is now general agreement in many countries that for the treatment of uncomplicated attacks of scarlet fever caused by the toxin of the scarlet fever streptococcus, and for the protection of susceptible individuals who have been exposed to infection, antitoxin is potent and specific. Its use is now widespread. The main interest has therefore shifted to the question of dosage and standardisation. Of the methods of standardisation which have been tried, three need human subjects—viz., the Schultz-Charlton test, passive immunisation, and the Dick method of "skin neutralisation"; in two methods animals are used—viz., the Wadsworth-Kirkbride skin neutralisation in goats and the Parish-Okell rabbit test. If a test involving the use of animals has an error no greater than those needing human subjects, the animal test will presumably gain acceptance. The various methods are being compared in many laboratories but no critical comparison appears yet to have been published. Dr. R. Cruickshank elsewhere in this issue concludes in favour of the skin neutralisation method in human beings and the rabbit test, though his own careful observations on the duration of passive immunity show that this also is a good method of titration, for the effect of a dose of 2·5 c.cm. can be clearly differentiated from that produced by twice the dose, the patients in the latter group remaining negative to the Dick test for a longer period. This method would provide those in isolation hospitals with a means of testing the serum they use, for 5 c.cm. of a good serum will, as he [1] and D. McClean [2] have shown, keep the majority of patients negative to the Dick test for seven to ten days and will protect contacts from infection with scarlet fever. Parish and Okell [3] state that an average concentrated serum will in a dose of 0·25 to 1 c.cm. protect rabbits against the acute illness produced by the injection of culture of scarlet fever streptococcus. This method they use for measuring the strength of sera. Both Cruickshank and R. E. Dyer [4] discuss the difficulties of the skin neutralisation test. Not all Dick-positive subjects are suitable for the test, because of serum sensitiveness, and the readings are not easy. In U.S.A. an official unit based on this method has been fixed and a minimum content of antitoxin prescribed. No English official unit has yet been adopted. Meanwhile, the general experience in England that the sera available are efficient in the treatment of scarlet fever and for the passive protection of contacts is evidence that the methods of titration of these sera in use in the various serum institutes are serving their purpose and ensuring supplies of satisfactory sera.

BRITISH MEDICAL ASSOCIATION

ANNUAL MEETING AT CARDIFF.

(*Continued from p. 250.*)

SECTION OF SURGERY.

UNDER the presidency of Prof. A. W. SHEEN a later of Mr. A. J. WALTON, a discussion on the

DIAGNOSIS AND TREATMENT OF SPINAL CORD TUMOURS

was opened by Mr. DONALD ARMOUR, who limi himself to tumours arising from the cord, the spi nerve roots, and the meninges, and chondromata the intervertebral disc. Clinically they caused paraplegia by compression. More than three-four were extramedullary and the intradural were m frequent than the extradural by three to one. intradural tumours about two-thirds were do or dorsolateral in position. The course of the dise was usually slow and chronic and divided into th stages: (1) of root symptoms, usually unilateral; of Brown-Séquard paralysis; (3) of complete co pression, paraplegia, or bilateral paralysis. symptoms generally appeared in the following ord Peripheral pain, increase of reflex activity below point of compression, paralysis, loss of sensibili and loss of reflex activity with flaccid paraly The commonest early symptom was localised, rec ring and persistent pain, referred to the course the nerve involved and attributed to innumera conditions in the body and limbs. Pain in the b might be the only complaint for a long time, especia with lumbosacral and cauda equina growths. Press on the sensory tracts of the cord might cause pain remote parts of the body before any motor or sens changes could be discovered. Paræsthesiæ of vari kinds might occur, at the level of the tumour, fr root irritation; above the level, from pressure of held-up cerebro-spinal fluid, or from sympathe involvement; or below, from irritation of sens tracts. Objective sensory changes were usua absent in the early stages and later depended on amount of compression or destruction of the tra In extramedullary tumours there was some dis ciation of sensations below the level of the tumo while all types of sensation were equally involv in intramedullary growths, in which also maximum sensory disturbance was often at a below the segmental level. Tactile sensation less affected than pain and temperature. In tumo of the conus and cauda equina the sensory disturba was usually bilateral and asymmetrical. Subject motor disturbance usually followed subjective sens symptoms and was progressive. In high tumo the order of limb involvement was almost alwa homolateral upper limb, homolateral lower li contralateral lower limb, contralateral upper li The irritative stage, with tremor, muscular tens and spasms was generally over by the time the pati came for examination, or was masked by a degen tive paralysis of the corresponding muscles wit diminished tendon reflex. When the tumour be to exert further pressure on the cord direct indirect spinal symptoms appeared and were of gr diagnostic value. Very often a minimal stimu produced the "mass reflex." Bladder loss usu preceded rectal loss by some time. The patholog effects of the actual pressure on the cord were ex ordinarily limited, as was shown by the recov after removal of a large tumour. Paraplegia flexion followed paraplegia in extension which mi however, be a very short stage.

Localising Symptoms.

Nystagmus might appear in high cervical tumo and bulbar symptoms occurred occasionally. Inte pain up the back of the neck and head might ca a clinical picture suggestive of caries or spasm torticollis. Involvement of the phrenic roots m cause diaphragm paralysis.

In lower cervical tumours four root syndromes might appear—Erb-Duchenne type; a middle type with atrophy of the triceps; Aran-Duchenne type and Dejerine-Klumpke type.

Lower dorsal tumours might simulate abdominal disease and lumbar tumours might show multiple root signs with atrophic paralysis. Tumours of the cauda equina caused intense pain radiating over the perineum, perineum, and back of legs, and trophic lesions were common.

Atypical clinical forms were of four kinds. Those with purely medullary symptoms showed paraplegia without any signs of root involvement. Those with purely root symptoms were like ordinary neuralgias. When there were multiple tumours, two root syndromes were superimposed. The vertebral form was marked by intense and diffuse pain and was often diagnosed as Pott's disease.

There was no symptom which occurred exclusively with any one kind of tumour. The symptoms differed in sequence, duration, and time of onset according to the localisation of the growth. A short history was in favour of the more rapidly growing extradural variety. Bony changes were rarely seen in intradural tumours and were common in extradural. Other features of extradural tumours were sensitiveness to pressure over the spine and absence of root pain and xanthochromia; lumbar puncture might cause sudden and marked increase in symptoms. Great excess of protein in the lumbar fluid combined with completely normal cisternal fluid or a "reversed" Brown-Séquard syndrome was in favour of an extradural growth. As a rule, intramedullary tumours were characterised by less frequent root pains, less spastic paraplegia, and more common amyotrophic phenomena, a more marked alteration in painful and thermal sensibility and a typical and clearly shown dissociated anæsthesia. In favour of a diagnosis of intramedullary tumour was: a preliminary stage of root pain, slow but continuous development of paralysis in motor and sensory function, a growth more breadth rather than in length, fairly long persistence of a Brown-Séquard syndrome, marked spasticity persisting after the appearance of complete paraplegia with Babinski's sign; symptoms of motor root irritation and absence of signs of atrophic degenerative paralysis, and of trophic troubles, and the "loculation syndrome" in the cerebro-spinal fluid.

Combined cisternal and lumbar puncture was a diagnostic aid revealing below an area of compression, xanthochromia, increased protein and other substances, and occasionally spontaneous coagulation. The replacement of cerebro-spinal fluid by air caused nausea, pain, or collapse in cases of spinal block. Lipiodol injection was not very reliable, and there might be sensory lipiodol dissociation; its greatest field of usefulness was where the sensory level was not well defined.

There was only one treatment—operation—which commanded correct diagnosis and precise level localisation. Segments of the cord did not correspond with the vertebræ of the same name, and there were also individual differences. The operation of choice was laminectomy as developed by Victor Horsley, with the patient in the lateral position, under intratracheal ether. (Mr. Armour then described the technique in detail.) French authorities were more enthusiastic than others in the use of X rays and radium for operable growths, but even they were cautious and warned against exaggerating the curative value.

Dr. G. RIDDOCH said that diagnosis must ultimately rest on the existence of a progressive paraplegia with signs pointing to root involvement. Remote signs might be absent at a stage when diagnosis was quite possible, or focal signs might be absent throughout. Clinical features came first in diagnostic significance, followed by investigation of the cerebro-spinal fluid and vertebral signs and, in selected cases, by other methods for determining the patency of the subarachnoid space. The paraplegia developed in a certain definite way; the first stage was a spastic paraplegia in extension, with a weakness that was more flexor than extensor, and which appeared more in the lower limbs, with downward pointing of the foot and toes. The reflexes were all increased and Babinski's sign was present. Homolateral extension of the whole limb might be evoked by stimulating the leg below the knee, and the gait was spastic. In the second and graver stage, of paraplegia in flexion, the flexion reflex dominated the reflex picture and could be obtained by stimulation of any part of the limb, and the mass reflex might be evoked. In the third stage there was flaccid paralysis. The diagnosis of the level of the growth was made primarily on focal signs, which might be of root or of segmental origin. The former pointed definitely to the segment involved, but the latter did not. Motor signs were usually of less value. Diagnosis was most difficult when there were no focal signs and reliance had to be placed on the often equivocal sensory phenomena and the motor and reflex signs, which were not much help. It was necessary to ascertain the point where normal sensibility changed into abnormal, and not merely the highest limit of complete anæsthesia; moreover, the obliquity of the fibres had to be taken into consideration. The appreciation of tuning-fork vibration was often valuable and might be impaired when the posterior columns were involved. On the whole, intramedullary tumours were more often cervical or lumbosacral in location and extramedullary ones about the regions of the enlargements. With the former, remote and focal signs appeared more or less together, while with extramedullary growths the focal signs might appear long before there was any paraplegia.

Lipiodol Injections.

Sir PERCY SARGENT showed lantern slides of different varieties of tumour and X rays of lipiodol injections. Lipiodol, he said, sometimes caused severe root pain and might have serious after-results. When successful it was very useful, but the better the neurologist the less often would it be necessary and it should be used less rather than more. Intramedullary tumours usually extended over many segments, producing an elongated block, in contrast with the local block of extramedullary growths. By a cisternal injection and a lumbar injection with the patient inverted, it was possible to map out an area of block. The prognosis of patients with intramedullary tumours was not hopeless—he had seen three recoveries. The operative mortality-rate was very low; the worst areas were between the second and fifth dorsal, where serious cardiac, gastric, or intestinal disturbance might be caused. The excellent recovery depended on the facts that compression had been very slow, that the bladder function was usually involved very late and very slightly, and that bedsores were very rare; there were therefore no septic complications.

Mr. LAMBERT ROGERS recorded six cases of spinal tumour from the Welsh National School of Medicine, one in a girl of 16, who had made a remarkable recovery. The tumour had contained many psammoma bodies and also masses of true bone, a very rare finding which afforded evidence of the essential similarity of cranial and spinal meningiomas and supported the mesoblastic derivation of membranes.

Mr. G. JEFFERSON said that his experience of spinal cord tumours was that they were practically painless and patients complained of spastic paraplegia. The syndrome of cord compression followed in a definite sequence, first a disturbance of motor power in the legs and then sensory changes of a particular kind, notably dissociation. He then showed a number of charts demonstrating the results of investigating the cerebro-spinal fluid by the Queckenstedt method.

The Importance of Early Diagnosis.

Mr. WILFRED TROTTER spoke for the common man, and said that the diagnosis was often missed in the early stages, especially when the disease began as

unexplained pain, which was almost always diagnosed by some meaningless phrase, varying from year to year with the fashion—neuritis, sciatica, arthritis, fibrosis. That was the form in which spinal tumour came before the panel doctor. The commonest tumour was the neurofibroma, and this essentially began with root pain, without any physical signs. If it were then diagnosed, treatment would be early and almost invariably successful.

Mr. H. ADAMS quoted a case of psammoma of the sixth dorsal region, which began as a painless limp. He suggested that the neurofibroma type might be the cause of pain, while the psammoma and endothelial type of tumour was the cause of spastic paraplegia.

Mr. STANLEY FOSTER recorded several cases with no paraplegia, only pain; one had been diagnosed as neurasthenia, and another as Pott's disease and disseminated sclerosis successively.

Mr. R. BROCKMAN said that cases of unexplained pain were the most difficult to diagnose, and instanced one woman with unilateral pain radiating from the lumbar region round to the pelvis. She had had an inflammatory mass removed from her abdomen and a subsequent nephrectomy without relief, and died suddenly after a profuse hæmorrhage from a spinal tumour. Cases of "curious pain" should always suggest spinal cord tumour.

Mr. WALTON said that the slower the course the better the prognosis, as the ultimate results depended less on the presence of a tumour than on the damage it had done, which was proportional to the rapidity of its growth. All cases should be operated upon at once. He agreed with Mr. Armour's technique. What operative risks there were were the accidental risks of all operations.

TREATMENT OF GANGRENE.

Mr. SAMPSON HANDLEY (London), in opening the discussion, said he proposed to confine his remarks to more recent methods of vasomotor surgery in relation to gangrene, and gave a brief history of the subject. He described Leriche's method of performing periarterial sympathectomy and stated that this surgeon had had successes in various conditions, but he did not perform his operation for gangrene. According to Prof. Leriche, after sympathectomy there is a local contraction of the artery, and for some hours pulsation is feeble and the limb is colder than its fellow. This is followed by elevation of the temperature of the limb and of the arterial pressure, and by increased amplitude of the pulse for from three to four weeks.

The speaker then drew attention to his method of alcohol injection, which he believed was a definite advance on Leriche's operation, and claimed that in certain cases it will avert threatened gangrene, or arrest the spread of senile gangrene already present, and so obviate amputation. The technique used is to expose the femoral artery in Hunter's canal for 1 to 2 in. With the finest possible hypodermic needle 2 to 3 minims of alcohol are injected at four points spaced round the artery, the needle being inserted obliquely and nearly parallel to the vessel. When the injection is complete a whitish band about ½ in. wide should be seen round the artery, but no constriction takes place. The effect of alcohol injection is that the foot in successful cases becomes warmer almost at once and the vasodilatation may last for a year or more, whereas it is stated to pass off in a few weeks after Leriche's operation. Mr. Handley mentioned some criticisms of the method and stressed the difficulty of making a proper selection of cases at present. In regard to indications, he would advise it strongly in cases of threatened or incipient gangrene of a lower limb, but would prefer to employ it in the prodromal stage. He considered it useless in Buerger's disease and of doubtful value in Raynaud's disease. Finally, he claimed that alcohol injection was a distinct advance on Leriche's operation, and appealed to medical men when first consulted for symptoms of arterial dystrophy to allow vasomotor surgery a fair field in its attempts to avert the onset of gangr and the loss of a limb.

Mr. PHILIP TURNER (London) said he would con himself to the clinical aspects of periarterial sym thectomy, which he had performed eight tir twice by operation and six times by alcohol inject Of these, three were very striking successes wh he narrated, three were temporarily improved, two, whose general condition was very bad, d Mr. Turner pointed out that following sympathect the following clinical effects were seen whate their cause—namely, increased warmth of the f relief of pain, disappearance of swelling, rapid for tion of a line of demarcation, and improvement general condition. Mr. Turner said this opera was a valuable addition to amputation, which m be avoided in 25 per cent. of cases and delayed 50 per cent., and in his opinion it is particul indicated in early cases of senile gangrene and sh be carried out as soon as the diagnosis is made.

Mr. E. G. SLESINGER (London) could not a that sympathectomy acted by dividing the v constrictor fibres; all modern evidence, he said, against this. He suggested that what were divi were the afferent sensory nerves of the arteries, the effect of sympathectomy was due to breal the reflex arc. He discussed arterial pain compared the pain of angina pectoris and abdom with that of incipient gangrene. In his experi the operation succeeded when there was reflex sp in addition to organic narrowing. He could no advantage in the method of alcohol injection sympathectomy which he had performed 25 ti with no mortality. Finally, he urged that sym thectomy should be tried in all painful cases organic vascular disease, since it would relieve almost certainly and might, in addition, impr the circulation.

Mr. W. A. COCHRANE (Edinburgh) had trea cases of gangrene by exposing the main artery rubbing it with gauze, and had had successes. considered it of no value in endarteritis obliter but had found temporary benefit in varicose ul

Sir WILLIAM WHEELER (Dublin) had no experi of alcohol injection. He related cases of thron angiitis obliterans in which he had performed s pathectomy with no benefit and with no relie pain, and he stressed the importance of remo the whole sheath.

Mr. R. STL. BROCKMAN (Sheffield) put in a st plea for alcohol injection on the ground of simpli which brought it within the compass of every surg He considered it of value as a preliminary amputation.

Mr. HANDLEY, in replying, mentioned the pos danger of absorption of toxic materials from the gangrenous part as the result of vasodilatation operation.

FALLACIES OF X RAYS IN ABDOMINAL DIAGN

At a discussion held jointly with the Sectio Radiology, Mr. H. J. PATERSON (London) begar pointing out that medicine, being essentially an laboratory methods can never replace clinical ob vation. The chief fallacies as regards surgery m be grouped as: (1) those incidental to X rays those due to errors of technique; (3) those of direction; (4) those of interpretation. Under the speaker said that X rays exaggerated s and a better method of estimating this was the cha method; a further fallacy under this head spasm. Duodenal ulcers were seldom shown X rays, but often inferred when not present, whether gastric ulcers were shown depended on size and depth. Under fallacies of technique instanced the need for exposures in different posit and the importance of having the stomach filled with barium. Fallacies of misdirection co of diverting the attention to some abnormalit less serious import than the main disease. The group of fallacies of interpretation were nume and cases were mentioned of error in connexion

ll-stones, ureteric calculi, appendicitis, gastric er, adhesions, &c. Mr. Paterson said an insidious lacy was the claim that healing of a gastric ulcer uld be shown by X rays. Ulcers are stated to al in a few weeks after alkali treatment, but is e evidence good enough considering the inter- ttent nature of the disorder? Finally, the opener d he did not question the utility but the infalli- ity of X ray diagnosis.

Dr. F. HERNAMAN-JOHNSON (London) stressed e advantage of X rays over charcoal in localising sis of the bowel. In regard to spasm he would ld that spasm persisting after full doses of bella- nna shows some lesion in the alimentary tract. ilure to find organic lesions does not prove their n-existence, and a negative X ray can only exclude ss deformity. He objected to including fallacies misdirection, as it is important to demonstrate y definite lesion. Fallacies of interpretation must ays remain and no radiologist could differentiate X ray evidence only between an inflammatory np and carcinoma. It is important for radiologists indicate which of their deductions depend on ray findings and which on examination and tory. The speaker pointed out the importance not calling an appendix normal because X ray amination does not incriminate it, and stated that pelvic cæcum which does not rise on a barium ema and which contains residue after 24 hours en means appendicitis.

Dr. A. F. HURST (London) said the diagnosis of stric and duodenal ulcer depended largely on the ll of the radiologist and in experienced hands uld be right in 90 per cent. of cases. He would ver diagnose gastric or duodenal ulcer without ray evidence and the same applied to carcinoma. his opinion, if there was no obstruction, all gastric ers would heal if treated medically, provided treat- nt was sufficiently long and thorough, and their heal- g could be shown by X rays. Dr. Hurst mentioned e fallacy by which a not uncommon diverticulum the region of the cardia is mistaken for ulcer.

Mr. W. MCADAM ECCLES (London) stressed the portance of a complete radiological examination, d mentioned cases where incomplete examination ld led to unnecessary removal of the appendix.

Prof. A. FULLERTON (Belfast), after pointing out e necessity of piecing together the evidence of rious investigators in order to make a diagnosis, scussed the value of stereoscopic X rays in differen- ting phleboliths and calcareous glands from inary calculi.

Sir WILLIAM WHEELER appealed to radiologists to llow-up operations performed on cases they had seen, d said it was important not to give too definite negative report lest further observation of the case ght be discouraged. Personally, he thought there s no such thing as medical treatment for chronic stric ulcer.

Mr. RENDLE SHORT (Bristol) spoke of the value coöperation between radiologist and surgeon and the difficulty of proving a negative. In his experi- ce, if the clinical diagnosis and the X ray diagnosis fered, the X ray diagnosis was more often the rrect one.

Dr. T. I. CANDY (Newport) said that cases were en sent for barium meal examination too casually d without adequate notes. He asked that radio- gists should be given proper data and that it ould be remembered that they were often the only its of the team whose opinion was committed to per and could be held against them.

The Chairman, Prof. A. W. SHEEN (Cardiff), spoke the effectual coöperation that existed in his clinic, d said that negative X ray findings were often important as positive ones.

Dr. O. LEWELLIN RHYS (Cardiff) likened the diographer of some years ago to the race-course oster who had to name the winner before the race, d was abused if he failed to do so. Nowadays, e surgeon must bear his share of responsibility r a preoperative diagnosis.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

Sir THOMAS HOUSTON took the chair at a discussion on the

BACTERIAL FLORA OF THE INTESTINE IN HEALTH AND CHRONIC DISEASE

which was opened by Prof. J. CRUICKSHANK (Aberdeen), who surveyed the bacterial contents of the newly born and traced the changes that occur as age advances. He pointed out that the meconium is sterile, but organisms appear in small numbers in the first 24 hours after birth. During the first few days the organisms most frequently found are the *Staph. albus*, *Strept. fœcalis*, and members of the *B. coli* group. In the first sample of the meconium free fæces an organism of the *B. bifidus* type, appears. This latter organism increases in number and replaces other organisms to a large extent. If the child is breast fed, the *bifidus* type constitutes 95 per cent. of the organisms present. In artificially fed infants the predominant organisms are of coliform type. The fæces of breast-fed infants are distinctly acid in reaction, while those of artificially fed infants are alkaline or neutral. *B. bifidus* and organisms of the *acidophilus* type can survive exposure to highly acid fluids, which destroy coliform organisms. Thus the bacterial content of the intestine is related to the chemical reaction. Spore-bearing organisms are absent from the suckling's stool for the same reason. When breast-feeding is over opportunity is offered for the invasion of the alimentary canal by many organisms. The intestinal organisms have been grouped into two types, proteolytic and saccharolytic. Experimentally it has been found that a high carbohydrate diet gives a flora rich in *bifidus* and *acidophilus*, whereas a high protein diet gives a predominance of coliform organisms and spore bearers. Lactose appears to be the determining factor in the production of the saccharolytic type of flora. In 1915 Torrey reported favourably upon the use of lactose in typhoid fever, a most marked change occurring in the bacterial flora. The same treatment has been applied to conditions of intestinal origin in children associated with lassitude and anorexia with diarrhœa or constipation, in which there is proteolytic intestinal flora. A quicker transformation of the flora is achieved by combining lactose diets with cultures of *acidophilus* organisms. Prof. Cruickshank attributed the action of the sugar to its being attacked by *B. coli* and *B. welchii*, the various acid substances produced offering a suitable pabulum for the growth of *B. acidophilus*. This is suggested by the fact that direct inoculation of fæces into milk gives abundant growth of *B. coli* and enterococci in the first few days, but at a later date vigorous growth of *B. acidophilus* occurs. Sugars other than lactose have been tried but the above results have not been obtained. Starchy foods, however, tend to change the flora. The administration of animal proteins, on the other hand, produces a marked proteolytic or putrefactive flora. The speaker emphasised that to change the type of bacteria to the acid variety large quantities of lactose must be used, together with an *acidophilus* culture capable of surviving in the intestine. He further declared that the types of intestinal flora are most probably the result of abnormal intestinal conditions and not the cause of them. Dealing with the subject of auto-intoxication, he said that nothing had emerged from chemical or bacterial research in recent years to support the view that harmful substances are elaborated by bacteria in the intestine and then absorbed. It had been shown that a closed-off loop of intestine may contain very toxic material, but this is incapable of deleterious effects until the intestinal mucosa is grossly damaged. Experimentally produced intestinal obstruction in dogs tended to show that the resulting toxæmia is not so much due to bacterial disintegration above the obstruction as to mechanical disturbances below. In chronic ulceration there is frequently no evidence of intestinal toxæmia in many cases, although it might

be expected that absorption of toxic substances would take place at the site of damage of the mucosa. Many workers have held that intestinal mucus is an important defence against the invasion of organisms. Absence of vitamin A from the diet has been shown to produce changes in the mucous glands, and it is believed that these changes permit the entry of organisms normally held at bay. These views have been confirmed by further work in which animals have been fed on a diet deficient in vitamin A and subsequently found to be much less resistant to pathogenic organisms administered by the alimentary canal than other animals on a normal diet. It has been also shown that there is a relationship between the reaction of the intestinal contents and the occurrence of rickets, in this latter pathological condition the cæcal contents being alkaline while administration of cod-liver oil results in a change to an acid reaction. Deficiency in vitamin B is also associated with alkalinity of the cæcal contents. In considering the possible relationship of pernicious anæmia and intestinal toxæmia, it was pointed out that such relationship had not been proved. *B. welchii*, one of the organisms held responsible for the condition, is present in normal stools and no increase in pathogenicity or hæmolytic power has been found in pernicious anæmia. Further, bacterial toxins similar to that of *welchii* may be administered by the mouth without producing specific symptoms. Prof. Cruickshank strongly emphasised the importance of realising that an enormous variety of organisms can be cultured from normal fæces by various bacteriological methods, and he deplored the too often labelling of organisms as pathogenic with immediate recourse to the use of vaccines. Many of the organisms occurring in the intestine are ingested in the food and dust and are passively carried by the intestinal contents. Others find conditions suitable for multiplication. Before accepting an organism found in the stool as the causative agent even in acute intestinal disorders, much evidence other than its presence in considerable numbers, or that it shows pathogenic properties on injection into animals, must be presented. The organisms in the human intestine were compared with those occurring in the soil, the flora in each case being determined by the nature of the available food material. If the intestinal contents could be more frequently regarded as material which is outside of the tissues, and separated from these by a mucous membrane which is endowed with peculiarly selective absorptive powers, there would be less tendency to regard the bacterial flora of the intestine or its individual members as concerned in the causation of many chronic conditions in the human subject.

Discussion.

Sir THOMAS HORDER supported Prof. Cruickshank's contentions and said he was glad to receive academic support to his own beliefs on the subject. The standards at present used as criteria of pathogenicity of intestinal organisms are unsatisfactory. Further, there is no standard technique, with the result that clinicians are at a loss to understand the varying bacteriological reports on the same sample of material submitted to a variety of workers.

Prof. J. H. DIBLE (Cardiff) described a large series of investigations of intestinal organisms during the period of the war. In the first group of this series Morgan's No. 1 bacillus was extremely rare. There were no cases of dysentery in this group. In successive groups dysentery became a frequent occurrence and Morgan's No. 1 became proportionately more frequent. The criteria on which the diagnosis of hæmolytic streptococci is based was also carefully considered. Some methods show a large percentage of these organisms in the fæces in certain cases, but a more detailed and extended investigation throws doubt on the findings recorded. Prof. Dible also pointed out the extreme difficulty of determining the exact nature of a normal intestinal flora.

Dr. A. F. S. SLADDEN (Swansea) spoke from the point of view of a routine bacteriologist. He emphasised the need for clarity on this subje Regarding technique, he believed that material fr the mucosa rather than mixed fæces should be u in bacteriological investigations. Direct examinat of stools for micro-organisms he considered of doubt use. A new method of investigation is required, such a method must be short to be of value to clinical bacteriologist.

Dr. L. P. GARROD (London) had carried out a se of careful investigations in an attempt to establ what fraction of the intestinal bacteria in health disease is composed of streptococci. He was able show that a low carbohydrate diet was associa with a diminished number of streptococci. He unable to show that the bile in the intestine had effect on these organisms, neither did the chemi reaction influence the relative numbers. In cases pernicious anæmia, colitis, and chronic arthritis definite increase of streptococci could be fou Dr. Garrod believed that estimation of the numb of streptococci as an indication of pathogenicity misleading.

Dr. A. P. CAWADIAS (London) dealt with clinical aspect. He classified intestinal infection i extra-infection and auto-infection. The au infections may be of saccharolytic or proteoly type. He had obtained good results by the use vaccines. He said further that cases of au intoxication occurred with no symptoms of intesti disturbance. He considered the possibility of n anaphylaxis being the cause of these latter conditi should be given every consideration.

The CHAIRMAN expressed the opinion that percentage of streptococci found in the stools depe on the cultural method used. The discussion shown that no useful conclusions could be dra from a bacteriological examination of the stools w present technique. It would be, however, difficult convince clinicians on this point. An import point in favour of absorption of organisms from intestine is the presence of intestinal organisms remote parts of the body. The speaker had inve gated several cases in which the enterococcus believed to be the organism causative of lesions urinary tract and nose. An organism had b isolated from stools in cases of ulcerative colitis Burger and by Houston. This organism, believed be the cause of the associated lesion, is said by speaker to be of enterococcus type. He had obtained good results from vaccines in cases believed intestinal auto-intoxication of enterococ type.

Reply.

Prof. CRUICKSHANK, in reply, said it is necess to show that organisms or their toxins are absor before good results said to be obtained by vacci can be claimed to be due to antibodies. If chem substances are absorbed the formation of antibo to combat them is unlikely. He expressed doubt the benefits claimed from vaccine treatment. possibility of anaphylaxis as a resultant of distur intestinal conditions was worthy of consideratio

---

SECTION OF ORTHOPÆDICS.

UNDER the presidency of Sir JOHN LYNN-THO a discussion on

LOW BACKACHE AND SCIATICA

was opened by Mr. W. A. COCHRANE, who said t careful eliminative diagnosis left a large group wh was essentially orthopædic, and which included industrial lame backs. A painstaking and meticul routine examination was of the utmost importa Special attention must be paid to the anatom type of the individual. The slender, tall and lan or small and delicate patient was unfit for he work and subject to functional breakdown of back. The second point for consideration was impairment of the normal balancing mechanism bad posture. The lumbo-sacral joints in partic

re overloaded in heavy people with prominent ging abdomens, and the sacro-iliac joint was also osed to static insult from flat-foot, short leg, or a affection. When X rays revealed no intrinsic on of the lumbo-sacro-iliac region the need for urate diagnosis was acute. A negative X ray tograph did not warrant the assumption that re was nothing the matter with the patient, and eful reading of good stereoscopic radiograms often ealed a departure from normal in extrinsic lesions. cases of alleged injury the symptoms were usually of all proportion to the severity of the trauma. npression fractures of the spine sometimes followed nparatively minor injuries, and were often over- ked. A lateral view often revealed a lesion that l been overlooked in the antero-posterior view. A nplex and difficult problem was that of the relation- o of anatomical variations of the fifth lumbar tebra to backache and sciatica; was the associa- n causal or casual? As Osgood said, the abnor- lity was to be regarded as potentially contributory, t there was an undoubted connexion between the sence of abnormality and the occurrence and sistence of symptoms.

he most difficult problem in cases of injury was mental one. Malingerers, however, were not mon. The workman was often genuinely deceived o the true sequence of events, and, having little how for his symptoms, was apt to exaggerate.

Differential diagnosis was always difficult, and nite intrinsic pathological lesions of bone and t must first be eliminated. The chief points to noted were the general build and attitude of the ient; the presence or absence of the normal bar curve, of listing or lateral deviation of the ne, of restricted and painful movements, of spasm wasting of muscles, of swelling and points of derness, and the nerve function in the legs.

Clinical Classification.

Acute traumatic strain was a rupture of ligamentous muscular fibres with all the phenomena of acute ury. A lesion in muscle caused pain when the scle was thrown into action; a lesion of fibrous ue when it was put upon the stretch; a lesion one or joint on all movements of the spine. The tment was rest. A superadded infective focus ht keep up the disability, as would also poor ily mechanics and posture. While complete rest advisable for a torn muscle or aponeurosis, a ained joint should be made active as soon as sible.

General postural strain was a condition of general scular fatigue and ligamentous strain. The ient complained of dull aching in the shoulders low back, relieved by rest. There was usually r posture and fatiguing occupation. Treatment by rest, support, and postural re-education.

Lumbo-sacral strain showed itself by dull or acute n indefinitely localised over the lower spine and , chiefly on one side, often accompanied by tica, and generally relieved by rest. Forward ding was limited by spasm of the hamstrings, there was local tenderness on deep pressure and ion of the hip with knee extended was limited. T treatment aimed at flattening the lumbar spine rest, hot fomentations, and suitable exercises.

Sacro-iliac strain, in contrast to lumbo-sacral in, usually affected the slender, visceroptotic type h poor posture. Sacro-iliac subluxation was rare, sacro-iliac joint strain was common. There was rred pain along the first and second sacral nerves, the tender spots were the inferior sacro-iliac ment, the sacro-sciatic notch, and sometimes the k of the sciatic nerve. The diagnostic points had n well set out by M. N. Smith-Petersen.[1] The tment was by rest and support, followed by heat, ssage, and education to flatten the lumbar spine undo the forward tilting of the pelvis. Mild cases were relieved by strapping, but usually a light brace and well-made corsets were required for a time. In more resistant cases the joint must be manipulated or ankylosed.

Combined pelvic joint strain.—Clinical features referable to both joints might be found together. An enlarged fifth lumbar transverse process causing pain usually responded to prolonged immobilisation, and support and operation was often successful. A better plan was to ankylose the lumbo-sacral region.

The Pathogenesis of Idiopathic Sciatica.

A mass of reliable evidence was now available to prove that many cases of sciatica could be traced to an anatomical lesion or abnormality in the lumbo-sacral region of the spine. There was localised pain and tenderness on deep pressure, sciatic scoliosis and pain referred along the sciatic nerve, which was not usually tender. Painful semi-sacralisation of the fifth lumbar vertebra was now a well-recognised entity. Abnormalities of the facets were not unusual, and poor posture still further reduced the size of the small foramen, already filled with the large fifth lumbar nerve. Treatment was by prolonged recumbency and immobilisation of the spine, combined with hyperæmia.

Mr. P. J. VERRALL said that in the backache of pregnancy less and less could be ascribed to uterine misplacements, though intrapelvic trouble might lead to pain referred along the third sacral nerve, much more superficial than the pain of sacro-iliac strain. A large factor in the production of this pain was the chronically over-distended rectum. The commonest causes of backache were: (1) Chronic overstrain of the erector spinæ or abdominal muscles. The muscles tried to maintain tone and then gave way, causing low backache in the case of the erector spinæ and lordosis in the case of the abdominal muscles. (2) Fixed flexed hip, due to irritation of the psoas by a chronically inflamed appendix or overloaded sigmoid. In these cases there was always tenderness in one iliac fossa. (3) Subinvolution of the sacro-iliac joints. Relaxation of these joints occurred during pregnancy and the menstrual periods. A subsequent involution similar to that of the uterus should occur. If this failed, backache was the result.

The typical deep tenderness over the sacro-iliac joints was always found, and the other sacro-iliac tests were positive.

In sciatica following pregnancy the question of how much was due to toxæmia and how much to trauma had to be decided. There was no doubt that both fourth and fifth nerves might be injured, as in maternal obstetric paralysis.

Mr. D. MCCRAE AITKEN said that with the present school medical inspection two most fruitful sources of backache—round shoulder and hollow back—were fast disappearing. Crush injuries were much commoner in young children than was generally believed, as they occurred when the bones were still largely cartilaginous. The long back was ill-supported by the erector spinæ and the importance of the oblique and quadratus lumborum muscles was often overlooked. Much of the pain was probably due to quadratus lumborum. "Where you have tension, there you have pain." It was at the origin of the muscles from bone that the strain occurred, and when the muscles gave way the strain fell on the ligaments, causing swelling and pain. In treatment, consideration must be paid to the existence of a toxic element, especially large bowel absorption. In "ricked back" a strip of muscle often got kinked over a bony process producing an elongated swelling. Manipulation would release this strip and give a dramatic cure.

Mr. WHITCHURCH HOWELL agreed that the efficient treatment of round shoulders, hollow back, and scoliosis would go a long way in preventing backache. He discussed the diagnosis of backache, which should be grouped under the headings of: (1) lumbago, (2) anatomical abnormalities, (3) trauma, (4) sciatica.

[1] Jour. Bone and Joint Surg., 1926, viii., 118.

The latter should be subdivided into true and false (due to pelvic lesions, arthritis of hip, &c.).

Mr. ROCYN JONES said that cases of backache might be divided into two groups—the traumatic and the postural (including the industrial lame backs). Both groups were complicated by infection. Difficulty in diagnosis arose between lumbo-sacral and sacro-iliac lesions. In lumbo-sacral lesions the pain was in the mid-line, there was rigidity of the lumbar spinæ, and the leg-raising test gave equal results on both sides. In sacro-iliac lesions the pain was below the posterior superior iliac spine, the lumbar spine was not rigid, and the leg-raising test caused earlier pain in the affected side. Stereoscopic X rays should always be taken. He stressed the difficulty in the differential diagnosis between sacro-iliac strain and early tuberculous disease. Until bony changes appeared in the latter differentiation was impossible. As regards treatment he agreed entirely with Mr. Cochrane.

Discussion.

Mr. ALAN TODD spoke of the causation of lordosis with backache in young men. Paralysis of the abdominal muscles due to muscular dystrophies, or anterior poliomyelitis and visceroptosis were the causes of several recent cases he had treated. Adequate supports by belts relieved these conditions, but in nonparalytic cases must be regarded as a temporary measure only. He emphasised the need for more orthopædically trained masseuses. This would only be obtained by making orthopædic surgery an essential part of medical training.

Dr. R. MANWARING-WHITE said that practitioners were to a large extent responsible for chronic backache, as the initial injury was often trivial and was then overlooked. The importance of toxæmias must not be underestimated.

Dr. W. A. MARRIS maintained that many cases were due to general ill-health. They were, in fact, "tired backs."

Dr. E. SOLLY complained that many patients were sent to him with a diagnosis of sciatica who were really suffering from an intrapelvic growth, frequently malignant, and not even in an early stage. These should be eliminated by careful rectal examination. Joint disease also often led to an error in diagnosis.

Mr. COCHRANE, in reply, said that he hoped to work on the lines indicated by Mr. Verrall—i.e., the relation of constipation, visceral tone, and other intra-abdominal lesions to backache. He pointed out the difference in the postural and kinetic use of muscles and the importance of physical training. He emphasised the importance of careful rectal examination of all cases.

VOLKMANN'S ISCHÆMIC CONTRACTURE.

Sir ROBERT JONES said that few cases were reported, because there was an idea that this condition conveyed some slur on the treatment; it ought, therefore, to be laid down most emphatically and intelligibly that ischæmic paralysis arose without any carelessness on the part of the practitioner. The essential pathological changes were degeneration of muscle and an increase of connective tissue in their substance, often with absence of sarcolemma nuclei. There was a round-celled infiltration and absence of transverse striation. The process was one of absorption and replacement of dead muscular tissue. The deformity was found mainly in children under 14 after injury to the elbow, and was due to pressure. About 80 per cent. of cases were associated with fracture. In a typical case the wrist-joint was palmar flexed, the carpometacarpal bones were dorsiflexed, the interphalangeals flexed, the hand pronated, and the elbow flexed. As a rule sensation and electric reactions were normal and the fingers could be straightened on flexing the wrist. The skin was blue, cold, and sometimes blistered and scarred. The muscles wasted rapidly and became hard and ropy; if the nerves were sufficiently involved conduction might be partially or wholly lost. Symptoms might appear a few hours after injury, and the damage w often completed in 48 hours. The contracture w preceded by numbness, swelling, muscular rigidi and sometimes intense pain. If untreated the def mity increased, from contraction of the fibrous mus and the disproportional growth of bone.

Mild Ischæmia.

Sometimes children were unable, months or ye after elbow injuries, fully to flex their fingers. Th cases suggested that a slight degree of ischæmia mi be quite common, just as blue, swollen fingers mi recover after the relief of pressure from spli Brooks's experiments supported the contention t the hæmatoma within the antecubital fossa mi produce venous block quite apart from bony placement, splinting, or bandaging. Jepson failed to produce anything but very tempor deformity by the application of splints, casts, bandages to dogs. A persistent lesion had only b procured by application of an Esmarch bandage a incision and ligation of the femoral vein. If wound were well drained the contracture could prevented. The chief factor, therefore, in Volkma contracture was a direct pressure from within without, causing acute obstruction to venous fl Inflammatory products added to the press J. J. Thomas had found nerve involvement in 60 cent. of his series.

Prophylaxis.

Under no circumstances, therefore, should an el be tightly bandaged. The fracture should be redu completely and at once. The backward displacem of the humerus must be corrected before putting arm up in flexion; a sharp projecting upper fragm often added to the internal venous obstruct Reduction was not easy if postponed for days. arm should not be bandaged to the forearm nor elbow to the side, but intelligent flexion was fectly safe. If a surgeon could not reduce the frac by manipulation he had better operate than leav All circular compression and splints should be avoi especially if there were much swelling. All c should be critically watched for the first few d If great pain, stiffening, swelling, lividity of fingers, or loss of voluntary movements appeared, arm should be released from all compression elevated. The methods of subcutaneous divisio the antero-ulnar side of the forearm and of mul incisions to evacuate the subfascial hæmatoma worthy of further trial.

The prognosis was always grave, and worst o when the nerve damage was excessive, when obstruction to circulation remained pronounced, when there was only mass movement in the fin and the wrist was fully flexed with the forearm in extreme pronation. Treatment of the establi condition was mechanical or operative, the aim t to keep the forearm supinated. The former lin treatment consisted in gradually extending first fingers, then the metacarpophalangeal joints, the wrist. Physiotherapy had an assured position should include radiant heat, contrast bathing stupes, gentle massage, and electrical stimulatio the muscles. When a nerve was divided oper was imperative, and the after-care was most impo in cases of tenoplasty. Myotomy and tenotomy not to be recommended. Free excision of the el joint might be indicated when there was contra of tendons and fixation of the forearm in pronati

Practitioners must insist on an X ray photog or a refusal of it in writing, and should warn patient of the possible serious results of an e injury: Volkmann's contracture and myositis ficans. Further, they should join a medical de union, for the law might be invoked whatever did.

Mr. W. ROWLEY BRISTOW pointed out that isch paralysis meant death of muscles, therefore faradic and galvanic reactions were lost; in milder cases they would be normal. Nerve s was worth while, even if the muscles were be

overy, as it restored gross sensibility. He emphad the fact that the position for setting up fractures he elbow was not "full" or "acute" flexion, but tial flexion across the chest.

Why the Forearm Only?

Ir. D. McCRAE AITKEN remarked that Sir Robert es never under any circumstances "stretched" a e "on splints"; he was most careful not to a limb up in any tension. Volkmann's contracwas one thing—primarily a congestion, a deposi of lymph, and an organisation of fibrous tissue ughout the muscle, producing strangulation; ve injury was another thing which might occur he same time and ought to be dealt with at once. suggested that the reason why the forearm was ticularly affected was that its muscles were remely highly organised with quick and fine ex adjustments to each other, and therefore ly vulnerable in their function. He quoted a which suggested that something depended upon ducation of the coördinating movements, and so n the development of muscles which might not erwise be restored to function.

Ir. H. PLATT put forward an anatomical explana of the susceptibility of the forearm muscles, which se from a small origin, and swept up obliquely, losed in a very tight compartment with a t of unyielding fascia. Between internal and rnal condylar groups the biceps tendon was rposed. In this "box" it was easy to get pressure tructing the venous return along the venæ comites he ulnar recurrent arteries. The median nerve, sing between the heads of pronator radii teres, vitably get strangled as the fibrous tissue conted. A great advantage of operation was that nerve could be freed and the muscles stripped the epicondyle, thus giving a very good start.

Ir. D. S. MIDDLETON recorded some investigations Volkmann's myopathy, particularly as it affected sternomastoid in congenital wryneck. Scar ue only occurred as a result of muscular death n the venous drainage was obstructed so that products of autolysis could not be removed by usual channels. They thus formed an irritating ign body which was dealt with by the usual cess of revascularisation and scar formation. ee or four days after venous ligature all the scles were invariably found cyanosed, swollen, and rotic, but a few months later some of them would found to have recovered. A striking thrombosis urred in the venous tree and was organised. bably the temporary interference with venous rn produced by ligature was not enough to cause osis, but was converted into a secondary perent interference by thrombosis.

natomically there was little connexion between deep and superficial venous systems of the foreus below the bend of the elbow, and the venæ nites of the ulnar arteries were much larger than se of the radial. At the bend of the elbow there a venous plexus that could be covered with a pence, and pressure on this meant obstruction to venous return from almost the whole forearm. profunda vein entered over the firm fibrous arch necting the radial with the humero-ulnar origin he flexor sublimis digitorum. A hæmatoma would e the veins down on to this edge and produce truction. Drainage operations therefore seemed sonable. Mr. Middleton mentioned that of José ges, of Buenos Aires, who freely divided all the neurotic sheaths in a zigzag fashion to allow ansion and free drainage. If thrombosis had ted, however, operation could not be expected give complete recovery. Mr. Middleton concluded t Volkmann's ischæmic contracture resulted from rference with the venous return by a hæmatoma a definite, localised spot in the antecubital fossa. depended therefore on causes associated with the ial injury, and methods of treatment—or the ence of treatment—played a minor part, if any, its production. It was not yet possible to say which cases would develop this complication, and it was doubtful whether that knowledge would materially assist its prevention.

Discussion.

Mr. TODD said that in view of the gross injustice which had recently been done to a member of the profession it was the duty of everyone to record cases of ischæmic paralysis occurring in the absence of any kind of splinting, strapping, or bandaging. He described two such cases, one an extremely bad and hopeless one following a fracture which had lain loose on a pillow without treatment, and the other, less grave, following dislocation of the elbow which had been reduced and sent away in a sling. He pointed out that it was never necessary to use an anterior splint or occlusive plasters for any fracture of the forearm; adequate posterior splintage gave perfect reduction. The teaching that a pad under the anterior splint helped to separate the bones of the forearm was false and pernicious.

Mr. HOWELL recorded some personal experiences, and pointed out that Volkmann's contracture was not a common thing, but that every injury of the elbow-joint ought to be regarded as a potential ischæmic paralysis. The treatment was to incise the hæmatoma, and to follow in detail Sir Robert Jones's method, by which independent joints were splinted with independent splints by an orthopædic masseuse. It was not possible to get more than a ¾-inch gap at operation without risk to the arterial supply. He described a modification of the collar-and-cuff method which ensured supination from the start.

Mr. P. J. VERRALL did not agree that ¾ inch was the maximum gap; the muscles could be stripped right across the interosseous membrane without any injury to vessels or nerves, provided always that this operation was never regarded as anything but an adjunct to Sir Robert Jones's stretching method.

Mr. ROCYN JONES agreed that the condition might come on without any splinting, and that this fact was one of the most important things to bring home to the public. He was glad to hear stress laid on the value of drainage in cases where there was œdema.

Sir ROBERT JONES, in reply, agreed that "acute flexion" was quite the wrong term for the correct position of fractured elbows, and that force should never be used in stretching the fibrous tissue—it was a real coaxing.

EXHIBITION OF DRUGS, SURGICAL INSTRUMENTS, FOODS, AND APPLIANCES.

THE usual trade exhibition was opened in the Drill Hall, Cardiff, on July 24th. A brief notice of the more important exhibits is given below, and will be concluded in the next issue of THE LANCET.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

1. *General Drug Exhibits.*

[46] Allen and Hanburys, Ltd. (Bethnal Green, E. 2), drew attention to the fact that their "Allenburys" infant foods now have added to them a proportion of synthetic vitamin D, ergosterol, so that they fully protect against rickets. Among the "Azoule" brand sterile hypodermic ampoules are sodium salicylate and urethane preparations for the treatment of varicose veins. Liver extract for pernicious anæmia is prepared in powder, tablets, and capsules. "Charkaolin" is a new preparation for fermentative intestinal infections, combining the absorbent properties of vegetable charcoal with the toxin-adsorbing qualities of "Osmo" kaolin. A new laxative is "Byno Chrismol" with a cold-water extract of senna pods. "Iodolysin" is a fibrolytic agent for rheumatoid arthritis and allied conditions.—[60] Bayer Products, Ltd. (19, St. Dunstan's-hill, E.C. 3), showed a series of their well-known preparations, such as "Adalin," "Luminal," and "Plasmo-

quine" for malaria, and drew special attention to "Compral," a rapid analgesic without hypnotic effect; "Phanodorm," an hypnotic for general practice without cumulative action; "Theominal," a combination of luminal and theobromine for arterio-sclerotic conditions; "Hexeton," a water-soluble synthetic camphor preparation for intramuscular and intravenous use; "Novasurol," a water-soluble preparation containing 33·9 per cent. of mercury in a complex non-ionisable form; and "Vigantol," a biologically standardised preparation of irradiated ergosterol, put up in pellets, ovoids, and a 1 per cent. solution in oil, of which 25 drops equals 10 mg. of vitamin D.—[39] Boots Pure Drug Co., Ltd. (Station-street, Nottingham), presented a series of pharmaceutical and toilet preparations, including "Columbrin." "Stabilarsan," "Thiostab," and "Bismostab."—[81] W. Bredt (41, Great Tower-street, E.C. 3) exhibited the "Ysates," dialysates from fresh plants, notably "Digitalysate," "Valerian-Digitalysate," and "Viscysate," prepared from *Viscum album* for conditions of high blood pressure. "Thilocologne," the preparation of ethyl chloride with eau-de-cologne, is now obtainable with a drop nozzle instead of a jet.—[20] Crookes Collosols (22, Chenies-street, W.C. 1) showed all their well-known colloidal preparations, such as argentum, iodine and manganese, and some new ones, including "Collosol Metallic Bismuth," a 5 per cent. preparation of finely divided metal which is usually absorbed within 10 days of injection, and "Collosol Mercurochrome" in dry scale preparation and sterile solution, standardised to obtain a definite percentage both of mercury and bromine. "Collosol Lactomagnesia" contains approximately 10 per cent. of magnesium hydroxide, and acts as an adsorber, a mild laxative, and a neutraliser without the evolution of gas. This firm also make some agreeable semi-toilet preparations, including "Collosol Argentum" tooth-paste and "Collosol Zinc" vanishing-cream.—[58] The British Drug Houses, Ltd. (Graham-street, N. 1), displayed their "Æther Puriss"; "Chloroform Puriss"; a non-clogging powdered liver extract, and their vitamin products, "Radiostol," "Radiostoleum," and "Radio-Malt," as well as "Caprokol," their urinary antiseptic; "Caprokol Antiseptic Solution S.T. 37," and their "Ergotoxin Phosphate," as used by A. Bourne and R. Burn.—[43] Burroughs, Wellcome and Co. (Snow Hill Buildings, E.C. 1) gave a prominent position to "Ephedrine," for asthma, hay fever, and leprosy; to "Allipol," the sodium salts of the less irritating fatty acids of hydnocarpus oil, and to "Avenyl," for leprosy complicated with syphilis. They also showed "Wellcome" liver extract and a representative display of standard drugs, sera, vaccines, and tuberculins.—[59] Evans Sons, Lescher and Webb, Ltd. (50, Bartholomew-close, E.C. 1), showed the various pharmaceutical specialties of this firm and the "Medi-soaps" manufactured by Charles Midgley, Ltd., of Manchester. Careful selection, preparation, and standardisation go to the making of this firm's gland products, which now include "Thymus Co.," "Mammary Co.," "Thyrosex Co.," and "Sexatones." This firm claim that their "Hepatex" is the cheapest and most concentrated liver extract on the market, one drachm being equivalent to two ounces of fresh liver. Their "Infundibulin" is now supplied in a special narrow-necked ampoule which can be opened without a file.—[35] Fassett and Johnson, Ltd. (86, Clerkenwell-road, E.C. 1), added to the well-known Angier's Emulsion and "California Syrup of Figs" a display of "Bemax," the new vitamin B preparation made from the detoxicated embryo of cereals.—[47] Ferris and Co., Ltd. (Union-street, Bristol), showed a series of fine chemicals and pharmaceutical preparations, particularly those of Martindale's "New Pharmacopœia"; also glandular products, cheap sterile accouchement outfits, and surgical dressings, specially set up in cabinets of "Ever-ready Caddies."—[27] Genatosan, Ltd. (Loughborough, Leicestershire), are very familiar for their "Sanatogen," "Genasprin" and "Formamint," and were displaying, as well as detoxicated ordinary vaccines, their local immunity produ including an anticoryza vaccine spray.—[24] Hoffmann-La Roche Chemical Works, Ltd. (51, Bo road, N. 13), draw special attention to their "Allon non-habit-forming hypnotic and analgesic, "Isacen" non-toxic synthetic aperient, which gra ally liberates di-hydroxyphenyl-isatin under influence of the alkaline secretions of the intest "Somnifaine" is a liquid hypnotic of the barbit group which can be administered orally, intramu larly, or intravenously.—[10] J. F. Macfarlan and (109, Abbey-hill, Edinburgh, and 32, Bethnal Gr road, E.1) showed a series of pure pharmaceut chemicals, including alkaloids and capsules of a nitrite; anæsthetics, especially ethyl chloride, dressings and ligatures.—[28] Oppenheimer, Son Co., Ltd. (179, Queen Victoria-street, E.C. 4), stre their new vitaminised preparations, such as "Vit a concentrate of the unsaponifiable fraction of liver oil, 100 times stronger than the natural This is supplied in "Palatinoids," equivalent to teaspoonful and one tablespoonful respectively the fresh oil. The little capsules make a most venient vehicle of administration for young child Irradiated ergosterol is also put up in "Palatino form, and "Malt and Vitad" is a preparation equ lent to a 25 per cent. cod-liver oil and malt, free from the unpleasant oily fraction. "Vitad also put into the well-known reconstructive f "Roboleine."—[41] Parke, Davis and Co. (50 Beak-street, W. 1) demonstrated their recogn remedies, including quinine hydrochloride and ureth solution for sclerosing varicose veins, and also m recent introductions, such as "Adrephine," aqueous solution for local use, combining the r relief of adrenalin with the sustained action ephedrine; "Metatone," a tonic elixir contai vitamin B, nucleinic acid, and glycerophospha and "Paroidin," a standardised extract of bo parathyroid glands for injection. "Oxytocin" is pituitary substance that acts on involuntary mu and "Vasopressin" is the pituitary pressor princ These two preparations will soon be on the ma Puerperal septicæmia streptococcus antitoxin is a able for prophylaxis and therapeusis, while the s of "Immunogens," originating in the P., D. and Laboratory, is now a long one.—[50] The Sa Chemical Works (5, Wigmore-street, W. 1) had view their well-known products "Femergin," "H mine" and "Bellafoline." "Allisatin" is t tasteless preparation of garlic. "Calcium-Sand is obtained from an oxidation product of glucos a special process and contains 13 per cent. of l "Sandoptal" (isobutyl-allyl-barbituric acid) i new safe hypnotic, well tolerated by the aged.— Schering-Kahlbaum, Ltd. (3, Lloyd's-avenue, E.C emphasised the value and safety of their non-nar analgesic "Veramon," and introduced "Solgar a new gold product of low toxicity, particularly u in leprosy, a 15-g. dose of which can be given safety. Two other new products are "Vasa camphoric acid salts of mandragora alkaloids, train, air, and sea sickness, and "Synthalin B much less toxic product than the old Synth "Atophan Balsam" is an amyl ester of "Atoph for inunction.—[54] W. A. Wharram, Ltd. (34, L lane, Leeds), make several popular pepsin preparat such as "Liq. bismuth co. c. pepsin," and very n other therapeutic products. Mention may be r of ephedrine tablets for oral administration; "Lir heroin hydrochlor. c. turpin. hyd."; "Syr. pulmo Co.," containing codeine phosphate, guaiacol, calcium phosphate; "Ung. analgesic," a combin of methyl salicylate, menthol, eucalyptol and camp and "Ung. stimulans," a mustard preparation u for rheumatic and neuralgic conditions.

2. *Special Drug Exhibits.*

[22] Anglo-American Oil Co., Ltd. (Albert-st N.W. 1), pointed out that the price of their "Nu has now been considerably reduced, and that "Mis

now supplied in an improved atomiser with a cap.—] Behring Institute (Marburg-L., Germany, and Bredt, 41, Great Tower-street, E.C. 3) were showing in their delightfully convenient "Vacuum Venule" the collection of blood samples, as well as "Yatren" pills, powders, and solutions, and "Yatren-Casein" protein shock therapy.—[49] Bristol-Myers Co. 2, Cheapside, E.C. 2) showed "Sal Hepatica," a ne regulator; "Ziratol," a non-toxic naphthaline iseptic; and "Ipana," a tooth-paste containing atol.—[6] G. W. Carnrick Co. (Brooks and Warton, Ltd., 40–42, Lexington-street, W. 1) needed introduction with their "Hormotone," "Trypen," "Secretogen," "Kinazyme," and other ndular compounds, but reminded the profession of care with which these are prepared and standised.—[67] Deshell Laboratories, Ltd. (Braydond, N. 16), argued once more the superiority of 'etrolagar" in its four forms: plain, unsweetened, aline, and with phenolphthalein. They laid stress its value for cleansing, evacuating, or retention mata, as it is miscible with anything, allays spasm, l holds the medicament in even dissemination on mucous surface.—At Stand [26] Eno's Fruit Salt meroy-street, S.E. 14) held its own, and was a eshing draught in the heat of the opening day.—] Ichthyol Co., Ltd. (18, Adam-street, W.C. 2), oduced "Albichthon," a colourless sulphur preation from the raw material of ichthyol, an effective tericide and clean to handle. Bristow's medicated chthyol" toilet preparations were also on view.—] Jeyes' Sanitary Compounds Co. (London) showed efined preparation of "Cyllin" for medical and gical use, with a Rideal-Walker coefficient for *typhosus* of 24 to 26; as well as capsules for stinal antisepsis, pastilles for the throat, soap der, and dental and shaving cream.—[7] Kaylene, . (7, Mandeville-place, W. 1), this year emphasised value of their colloidal silicate of alumina in ntile diarrhœa.—[71] Mond Staffordshire Refining , Ltd. (47, Victoria-street, S.W. 1), showed for the time the "Monsol" products: pastilles, ointnt, capsules, and anti-mosquito stick. The manuurers maintain that Monsol is practically nonic and can be used intravenously, and that a 00 solution is equivalent to 1/40 lysol at oneh of the price.—[84] The Saccharin Corporation, . (72, Oxford-street, W. 1), showed "Novocain" powder, tablets, and solution, and "Glaucosan," ew and very strong myotic prepared by Dr. C. nburger, of Berlin, for the treatment of glaucoma. 57] Scott and Turner, Ltd. (Gallowgate, Newcastlen-Tyne, and 211, Blackfriars-road, E.C.4), dispensed ndrews' Liver Salt" as in previous years with no of diminished activity.—[83] The Semprolin Co., . (18, Leather-lane, E.C. 1), prepare a wide range emulsions of high viscosity paraffin, of which naps the most interesting are those containing ectively guaiacol and salol. "Carmex" is a hing laxative mixture for infants. The firm are ll to find that the fact that their products are rely British is being appreciated by the medical ession.

3. *Toilet Preparations.*

3] Kolynos Inc. (Chenies-street, W.C. 1) and Pepsodent Co. (42, Southwark Bridge-road, S.E. 1) ented their well-known dental creams. The former showed a skin soap, liquid Kolynos for mouthh or gargle, and a denture powder, and the latter onstrated the rotary cleansing action of their ecoater" toothbrush.

Food and Drink.

2] Benger's Food, Ltd. (Otter Works, Manchester), layed the unique features of their food by a series lides, and reminded the profession of the value heir peptonised beef and chicken jelly, extract of marrow, and essence of rennet.—[44] Cadbury s., Ltd. (Bournville), emphasised the food value ilk chocolate, in every half-pound of which there one and a half glasses of full cream milk.—[51] son Ackermann-Laurence (St. Hilaire-street, Florent, France) gave special prominence to an exhibit of sparkling Saumurs; their Brut Royal is free from tannic acid and excess of sugar and alcohol, and is rich in ethers. On the same stand Messrs. Francesco Cinzano, of Turin, exhibited Italian vermouth free from preservatives, wormwood, and wood spirit.—[1] Energen Foods Co., Ltd. (Willesden, N.W. 10), showed their wide range of foods, originally prepared for diabetic patients but now used in all metabolic disorders (see THE LANCET, 1927, ii., 1337). Their "Endobran" biscuits are prepared according to Dr. Poulton's formula, with a low carbohydrate and a high fat content.—The attendance at Stand No. 95, that of William Gaymer and Son, Ltd. (Attleborough and London), showed no sign of diminishing during the whole of the Exhibition. Their "Special Dry Still" cyder is recommended for diabetics and sufferers from gout. Sufferers from heat benefited from their "Medium Dry" and "Medium Sweet."—[30] Granose Foods, Ltd. (Watford), showed their crisp, steam-cooked biscuits made from whole wheat.—[93] H. A. G. Coffee Co., Ltd. (40, Theobalds-road, W.C. 1), dispensed refreshing cups of their coffee, and showed alarming specimens of the caffeine which had previously been extracted from the bean.—[80] Horlick's Malted Milk Co., Ltd. (Slough, Bucks), have added to their well-known milk preparation a pleasant malted milk toffee, and lay stress on the value of their shadow-food, consisting only of two ounces of malted milk, four ounces of barium sulphate, and water. A new mixer was also demonstrated.—[65] Ingram and Royle, Ltd. (45, Belvedere-road, S.E. 1), showed the many mineral waters for which they are agents, including Vichy-Célestins, Contrexeville, Carlsbad, and Hunyadi János.—[23] Keen, Robinson and Co., Ltd. (Carrow Works, Norwich), testified to the continued success of Almata as a food for infants, invalids, and nursing mothers, and have issued a new prescription for the preparation of their "Patent Barley," so that the mother is saved the trouble of preparing barley-water first. Robinson's Groats, Robinson's Oats, and Keen's Mustard Ointment need neither introduction nor recommendation.—[8] Montgomerie and Co., Ltd. (Ibrox, Glasgow), showed Berina Infant Foods and Berina Malted Milk invalid diet, as well as Bermaline Bread.—[70] Nestlé and Anglo-Swiss Condensed Milk Co. (6 and 8, Eastcheap, E.C. 3) emphasised the vitamin content, bacterial purity, and dietetic value of their full-cream milk and malted wheaten products.—[45] Oxo, Ltd. (Thames House, Queen-street-place, E.C. 4), had a new preparation, "Liveroid," for pernicious and general anæmia. To their "Oxoid" standardised endocrine preparations they have now added an ovarian and a parathyroid.—[61] Alexander Riddle and Co., Ltd. (Bancroft-road, E. 1), demonstrated practically the refreshing properties of Stower's Lime Juice, Lemon Squash, and Orange Squash.—[11] Vitalia, Ltd. (17A, Boniface-street, S.E. 1), showed that "Vitalia" Meat Juice with soda-water could be a refreshing drink as well as a valuable food.—[82] West Surrey Central Dairy Co., Ltd. (Guildford), have added to their well-known "Cow and Gate" infant food two new preparations: "Brestol," a humanised cream of standardised fat, protein and vitamin content, and "Lacidac," an acid milk powder with a hydrogen-ion concentration when reconstituted of pH 4·6.

Surgical Instruments.

[46] and [63] Messrs. Allen and Hanburys, Ltd. (48, Wigmore-street, W. 1), called especial attention to their improved "St. Bartholomew's Hospital" pattern operation table, with new patent self-locking device for obtaining the Trendelenburg position, overhung by the "Pantophos" shadow-free light, in which heat and glare are eliminated. Among their large selection of stainless steel surgical instruments may be mentioned Souttar's craniotome, scalp clips, and steam cautery; Sargent's skull and laminectomy instruments; Tudor Edwards's thoracotomy instruments; Rowland's fasciatome for living sutures; Cope's universal "Duralumin" splint for Colles

fracture; gynæcological instruments made for Messrs. Comyns Berkeley and Victor Bonney, and rectal instruments for Sir Charles Gordon Watson; the "Rotanda" blood transfusion syringe; a unique ratchet for retractors; British cystoscopes, and the light "Oslite" head-lamp.—[9] Albert Brown, Ltd. (Chancery-street, Leicester), showed a selection of stainless steel instruments and electric sterilisers, in particular Georg Wolf bladder instruments with Zeiss optics, a true-colour filter being built into them so that the eye can follow the movements of a lithotrite and see the bladder contents in their natural colours without fatigue. An interesting head lamp for ear, nose and throat work was fitted w th an iris diaphragm and focusing lenses, so that the light could be intensified on a small area without dazzle.—[93A] Perhaps the most interesting exhibit in the whole show was that of Cameron's Surgical Speciality Co. (15, Stratford-place, W. 1). This apparatus provides, at a price well within the reach of the general practitioner, an endoscopic and inspection series which can be illuminated from any electric light plug and which the makers guarantee to be absolutely shock-proof and "fool-proof." The nasal sinuses can be trans-illuminated, root apices revealed, and foreign bodies detected; the retina can be lit up by pressing the bulb against the lower eyelid, and the veins are thrown into strong relief by pushing it into the soft tissues of a limb, so that intravenous injection in fat subjects loses its horrors. For the surgeon there are abdominal lights, which are guaranteed to withstand repeated sterilisation by boiling or steam pressure. The light used is of a wave-length peculiarly suitable for penetrating soft tissues. We advise every practitioner to inspect this for himself.—[76] C. W. Dixey and Son (13, St. Andrew's-crescent, Cardiff, and 3, New Bond-street, W. 1) showed a series of ophthalmoscopic instruments, particularly the Aves deviograph for testing the muscles of the eye.—[42] Down Bros., Ltd. (21 and 23, St. Thomas's-street, S.E. 1), included in their exhibit ox-bone plates and screws by Hamilton Bailey; Howarth's improved model of Chevalier Jackson's bronchoscopy and œsophagoscopy instruments; Souttar's counterpoised direct electric motor; Ivan Magill's portable intratracheal apparatus for anæsthesia; blood transfusion apparatus by Macintosh and others; and the "Up-to-Date" operation table with recent improvements.—[73] The Genito-Urinary Manufacturing Co., Ltd. (28A, Devonshire-street, W. 1), who are also agents for J. Eynard, Paris, showed a wide range of cystoscopes, bladder and kidney instruments, and diathermy apparatus.—[52 and 69] The Holborn Surgical Instrument Co., Ltd. (26, Thavies Inn, E.C. 1), had on view a large selection of modern surgical instruments in ordinary and stainless steel, including Kidd's female urethroscope; MacReynold's tonsil artery forceps; Guttmann's self-retaining vaginal speculum; the "Speclite" lamp, to clip on to the nose-piece of a shellite spectacle-frame, and the light, compact "Holborn" pocket head-lamp with elastic head-band.—[34] Mayer and Phelps (Chiron House, 59–61, New Cavendish-street, W. 1) pointed out their "Empire" operation-table, in which the Trendelenburg position can be obtained with perfect safety, and in which an improved lumbar bridge has been incorporated; Rowling's anæsthetic table; an outfit to supply a warmed atmosphere of either oxygen, nitrous oxide, or carbon dioxide, or of any percentage combination, with or without chloroform vapour; the "Chiron" fool-proof chloroform inhaler; Eadie's ligature forceps; and Canny Ryall's portable pelvic elevator.—[19] Rayner and Keeler, Ltd. (9, Vere-street, W. 1), showed various ophthalmoscopes and perimeters and a modified simple ophthalmic bracket which can be fastened above the patient's head and swung round in front of him. They also had on view various operating lamps and test types.—[12] The Surgical Manufacturing Co., Ltd. (83–85, Mortimer-street, W. 1), had a selection of new diagnostic instruments, including the Lilliput head-lamp; a new mercurial sphygmomanometer; a new combined ophthalmoscope, laryngoscope, and auroscope; Servic steriliser for dressings, and a convenient iodine container by means of which tincture of io can be carried about in a pocket and applied to patient without staining of clothes or instrument

(To be concluded.)

Special Articles.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Statistics of Venereal Disease.

IN December of last year a census of vene patients was taken by the Health Office and results have now been published. It is stated the registration schedules sent to the medical fession have been answered by 93·6 per cent. of general practitioners, 95·5 per cent. of the vene logists, and 97·5 per cent. of the hospitals and s toriums to whom they were sent, from which evident that the profession has taken great intere the inquiry. The figures show that in Germany t were 18,608 patients who first came for treatn within the period Nov. 15th to Dec. 14th. Of th 432 suffered from more than one venereal dise 76 per cent. had gonorrhœa, 2·1 soft chancre, 5·3 cent. primary syphilis, and 15·1 per cent. secon syphilitic symptoms. Compared with 1919 figures indicate a reduction by one half.

Phosgene Poisoning.

The regrettable accident at Hamburg, where escape of phosgene caused the death of al 20 persons and the illness of some hundred others drawn our attention to the properties of this poi Prof. Straub, of Munich, states that it is a labile substance much used in the chemical indust for instance, in the production of fuchsine. It easily be condensed into a fluid and on contact wet air this fluid is decomposed, developing chlo and hydrochloric acid. These corrode the bronchi produce broncho-pneumonia. Phosgene may enter the living cells and bring about their d and has thus a delayed effect on the organism. gas is produced when chloroform vapours com contact with a flame, and intoxication from cause used to occur sometimes in the days be operating theatres were fitted with electric light.

An International Conference on Scarlet Fever.

A conference of German and Russian me savants, medical officers, and hospital physicians held not long ago at Königsberg for the purpo exchanging views on scarlet fever. Dr. Dei (Berlin) said that in his experience antistreptoc serum had proved very efficacious, no patient ha died to whom the serum was administered in an stage of the disease. When serum was used comp tions also had been rarer and less severe. Korschun (Moscow) and Dr. Bardach (Od described methods of testing the efficacy of individual serum. The Russian members of congress reported that in their country prophyl injections had been made in some 100,000 chil and it had been ascertained that the prote lasted about nine months. This short duratic somewhat surprising as persons who have had sc fever are generally immune for a long period— for the rest of their lives.

Cerebral Research.

The German Institute for Cerebral Rese founded by the late Prof. Kräpelin, has now

nally opened. For a long time its financial basis s somewhat insecure, for the capital had been lost the inflation of currency; but Prof. Kräpelin ceeded in interesting the Rockefeller Institution he matter, and they furnished the necessary funds condition that a certain sum was collected for king the institute. The fund thus opened found scribers both in Germany and the United States, luding Baron Krupp, of Essen, and Mr. James b, of New York, and at last it has been possible open the new building. It has departments for opathology, topographical anatomy, serology, etics, and psychology respectively. A chemical artment under the celebrated analytical chemist, f. Willstätter, is to be opened in the near future. ides the lavishly fitted laboratories there are ms for collections and archives. At the opening emony, which was held in the presence of State municipal authorities, Prof. Bouman, of Utrecht, sented a sum of M.20,000 (£500) in the name of a ign committee. The Kräpelin gold medal was ferred upon Prof. Oscar Voigt, of Berlin, for his earches in the structure of the cerebral cortex.

Venereological Expedition to Russia.

The German Association for Aiding Scientific search, in coöperation with the Health Department of the Soviet Republic and the Russian Academy Sciences, has arranged an expedition to Russia for study of syphilis. It is stated that in Europe philis has undergone an alteration under the luence of civilisation. It is thus essential to study among a rather primitive population where it has n systematically combated for only a few years. a suitable locality the Burjato Mongolian Republic inated beyond Lake Baikal has been chosen. Two man medical men went there last year to select lace for the research and they found that a town led Kulskoe would be convenient for the purpose ause it possesses a hospital. The German Association has supplied the necessary apparatus and fitted out a large serological laboratory. The ssian Government have promised to care for the using and the maintenance of the staff, to have the pital enlarged and modernised, and to facilitate much as possible the work of the expedition. quired and hereditary syphilis will be studied by teriological and serological methods, and the results pared with those obtained in Europe. The edition will include syphilologists, internists, and rologists, and the German party, which will work ler the direction of Prof. Hessner, of the Clinic for nereal Diseases in Breslau, includes Dr. Klemm Dr. Patzig, of the Institute for Cerebral Research Berlin, Dr. Beringer, of the University Clinic for vous Diseases in Heidelberg, three women laboray assistants, and an engineer to look after the paratus. From Russia, where the Government ws great interest in the work, eight medical men, onging to the staff of the State Institute for nereal Diseases, will attach themselves to the edition.

Dr. Wentzler, head of an infants' home in Berlin, s that in his institution the throat of every infant, n if healthy, is daily examined by a nurse, redness any other abnormal condition being at once orted to the doctor. This makes it possible to ect suspected cases of illness at the earliest possible ment, and so prevent epidemics of diphtheria and rlet fever from developing. Owing to the recent rease of diphtheria observed here, he recommends t the same measures should be taken in the schools. nurse should be placed at the school entrance, ose duty it would be to examine the throat of ry child. Where any reddening was discovered rance to the school would be refused until the ld had been examined by the school medical cer, who would decide whether an infectious ease was developing, and whether the child might admitted to school.

MEDICINE AND THE LAW.

Imprisonment for "Nature Cure Practitioner."

MEDICAL practitioners are thinking quite as much of the public as of themselves when they deprecate the indiscriminate and unskilled use of ultra-violet ray and similar treatments. The possibilities of this kind of thing in the hands of amateurs are endless. During last month William Patrick Faulkner, a carpenter, was prosecuted at Marylebone Police-court on charges of obtaining certain sums by false pretences from Ernest Rose, another carpenter. It appeared that the two had entered into partnership and had opened a sun ray clinic and nature cure establishment in Praed-street, with a brass plate describing them as "Drs. Faulkner and Rose, nature cure practitioners and manipulative surgeons." Faulkner had made an agreement with Rose, which it was stated was signed "William Patrick Faulkner, M.D.," providing that each of them should put £50 into the concern and that they should share the profits. It was said that Faulkner told Rose he had just come from Ruskin College, Oxford, and was qualified as a doctor of medicine at King's College, also that he owned a house at Thornton Heath worth £1000. Believing these representations, Rose seems to have parted with about £130 in all. This included £4 which Faulkner seems to have obtained for the purpose of registering with the General Medical Council and 8 guineas for the purpose of registering with the L.C.C. Faulkner was not in fact on the Medical Register and did not pay the 8 guineas to the L.C.C. Mr. Wallace, appearing for the Director of Public Prosecutions, said Faulkner had been previously convicted for falsely pretending to be a registered medical practitioner, and also for obtaining money by false pretences. Mr. Wallace observed, as a warning of the dangers of sun ray treatment by unqualified persons, that one patient, who paid Faulkner a cheque for £6 and had treatment two or three times, was finally sent to hospital where she was found to be suffering from appendicitis. Had she continued her treatment with "Drs. Faulkner and Rose" much longer she would probably have ceased to require any treatment at all. Mr. Bingley, the magistrate, who passed sentence on Faulkner of three months' imprisonment with hard labour on each of two charges (making six months in all), agreed as to the grave danger to the public if people carried on such treatment unless properly qualified. The London County Council will presumably take note of the case. If their statutory powers of controlling such establishments are inadequate, they should be amplified forthwith.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. R. F. MacMahon is placed on Retd. List with the rank of Surg. Capt.

Surg. Comdrs.: R. J. G. Parnell to *Barham*, and as squadron medical officer and for specialist duties (on transfer of flag); and G. H. Hayes to *Warspite* (on transfer of flag).

Surg. Lt.-Comdr. S. R. Johnston to *Vulcan*, temp.

Surg. Lts.: J. J. Keevil to *Barham* (on transfer of flag); and C. H. Egan to *Warspite* (on transfer of flag).

Surg. Lt. (D) H. V. Pell to *Pembroke* for R.N. Barracks, Chatham.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lts. J. M. McC. Wright and J. Stephen to *Victory* for Haslar Hospl., for training.

Prob. Surg. Sub-Lts. E. G. Thomas, R. P. Davies, and D. A. Williams to *Victory* for Haslar Hosp. for training.

ROYAL ARMY MEDICAL CORPS.

Majs. to be Lt.-Cols.: H. T. Wilson, vice Lt.-Col. H. C. Sidgwick, to retd. pay; and R. C. Hallowes, vice Lt.-Col. (Bt. Col.) P. H. Henderson, promoted.

Capts. to be Majs.: R. D. Cameron (Prov.), W. J. F. Craig, J. Bennet (Prov.), W. C. Connell, and G. B. Wild.

Lts. to be Capts.: T. A. J. M. Dodd, R. A. Bennett, W. H. Carter, W. A. D. Drummond, J. G. E. Vachell, J. N. Atkinson, J. D. Corner, and J. T. Smyth.

Lt.-Col. H. C. Sidgwick retires on retd. pay.

Majs. A. W. Howlett, G. S. Parkinson, and J. Startin retire on retd. pay.

Temp. Lt. D. J. Allan relinquishes his commn.

TERRITORIAL ARMY.

Maj. J. H. Owens to be Lt.-Col. and to comd. the 161st (E. Anglian) Fd. Amb., vice Lt.-Col. (Bt. Col.) S. J. Fielding, vacated.

Maj. T. E. A. Carr, from T.A. Res., to be Capt., and relinquishes the rank of Maj.

W. H. Marston (late Surg. Sub-Lt., R.N.V.R.), J. K. Steel, and H. W. Walter to be Lts.

INDIAN MEDICAL SERVICE.

Capts. to be Majs.: Bishambhar Sahai, Manohar Lal Bhargava, D. V. O'Malley, Tirath Ram Khanna, and S. Dutt.

Temp. Lts. to be Temp. Capts.: Ganeshrao Venkatrao Gollerkeri, and Bercut Narain Khan.

COLONIAL MEDICAL SERVICES.

Dr. H. G. Holdbrook, Medical Officer, Federated Malay States, to be Senior Medical Officer, Selangor; Dr. W. H. Hart, Medical Officer, Federated Malay States, to be Senior Medical Officer, Perak.

Dr. S. P. Joseph, Mr. M. Jinadasa, and Dr. A. A. M. Weeraperumall, medical officers, to be Provincial Surgeons, Ceylon.

The following appointments have been made: Capt. P. H. Martin, Pathologist to the Institute of Medical Research, Federated Malay States; Dr. G. E. M. B. Dodds and Dr. C. E. M. J. Libert, Medical Officers, West African Medical Staff; Miss G. Lowe, Medical Officer, Nigeria; Dr. G. M. M. Menzies and Dr. W. Hunter, Medical Officers, West African Medical Staff.

DONATIONS AND BEQUESTS.—As the result of the recent Westminster Hospital Week, which was organised by representatives of the principal firms in Westminster, the institution has received £3500.—Mr. William Lyon, Carnoustie, left £500 each to the Dundee Royal Infirmary and the Forfar Infirmary to be applied to name a bed after him.—Mr. John Norman Dickinson, of Cockermouth, Cumberland, left £500 each to the Whitehaven and West Cumberland Infirmary and the Cumberland Infirmary, Carlisle, and £200 to St. Dunstan's Hostel for the Blind.—Mr. John Denniston Wilson, of Shaftesbury-avenue, London, and formerly of the Mercantile Bank of India, Batavia, Java, who left £57,188, after a number of private and other bequests amounting to £20,000, gave £1000 to the Hospital for Sick Children, Great Ormond-street, London, and the residue of the property to the executors for charities and hospitals.—Miss Alice Isabella Avery, of Athelney, Torquay, besides other bequests, left over £7000 to charities, including £1000 each to the Edinburgh Medical Missionary Society and the Children's Emigration Homes, and £500 to the Birmingham Medical Mission.—The Manchester Board of Guardians have decided to contribute £1000 towards cancer research.—Mr. Edward Palgrave Simpson, of Durham Villas, Phillimore-gardens, London, left, among other bequests, £2000 to St. Dunstan's Hostel for the Blind; £1200 to the Jenny Lind Infirmary, Norwich; £1000 each to Dr. Barnardo's Homes and the National Lifeboat Institution; £500 each to the West London Hospital, the National Industrial Home for Cripple Boys, Kensington, the Royal Hospital for Incurables, Putney, S.W., the Kensington District Nursing Association, the Church of England Homes for Waifs and Strays; £250 each to the Children's Country Holiday Fund, the Girls' Friendly Society, and the Holiday Cottage, Aston Clinton; £200 to the Norfolk and Norwich Hospital; £100 each to the After-Care Association, the Institution for the Indigent Blind, Norwich, the Eye Infirmary, Norwich, the Children's Convalescent Home, Lowestoft, and to the National Benevolent Institution.—Mr. Arthur Frederic Pope, of Manchester, among other bequests, left £500 to the Northern Counties Hospital for Incurables, £500 to the Manchester and Salford Hospital for Skin Diseases, and £500 to the Manchester Royal Infirmary.

Correspondence.

"Audi alteram partem."

SMOOTH AND ROUGH VARIANTS OF BACTERIA.

To the Editor of THE LANCET.

SIR,—The letter by Surgeon-Commander Sheldon Dudley in THE LANCET of August 4th emphasis the present difficulties in attempting to analyse a classify the observed variation in bacteria. Nam such as "smooth" and "rough" given to spec instances of variation in the intestinal group ha perhaps rather rashly been transferred to sup ficially similar variants in other groups. Morpl logical studies of colonies by Baerthlein and othe though of great importance in establishing that su variations do occur, do not of themselves lead ve far on account of the great variety of the coloni the uncertainty of the criteria based on colo morphology alone and the gradations betwe different types of colony.

It was in the hope of advancing the study variation further along the path indicated Baerthlein that the present writer described a p ticular kind of variant distinguished by three son what diverse characters—namely, irregularity of t edge and surface of the colony, agglutinability in s solution, and alteration in the agglutination serum. Though this group of characters wh constituted the variant called "rough" in *Bacil dysenteriæ*, *B. typhosus* and allied bacteria appears represent a fundamentally changed race, still t change is not always complete and the three charact may to some extent vary independently. This a applies to a fourth character—absence of patl genicity—which has since been determined in cert "rough" variants. The independent variability the characters is perhaps often not so much due the want of uniformity in the elementary factors a given variant as to the observed characters r being sufficiently elementary to correspond exac to the fundamental factors. Further observation a scrutiny tends to reveal the really essential ur which themselves are concerned in variation.

As an example of diverse variants which superficially alike may be mentioned the "medu head" colonies in *B. anthracis*, *B. subtilis*, strep coccus, and occasionally in *B. typhosus*. The appe ance of this form of colony is due to growth of bacteria in long chains or threads often without a other constantly associated change in the antige or other characters. Such colonies are probably part responsible, as has recently been remarked F. W. Andrewes, for the different observations regards virulence, &c., obtained with colonies wh appear alike. On account of the irregularity surface "medusa-head" colonies have sometimes b called "rough" and a resemblance in virulence, a genic properties, &c., to other "rough"-look colonies, which are essentially very different, expected unwarrantably. It is surely undesirable decry the quest for "laws" or "rules" in variat because apparent exceptions occur, considering complicated biological processes involved.

The promised publication by Commanders Dud and Parker on the toxigenicity of different col forms of *Corynebacterium diphtheriæ* will be welcon by other bacteriologists, especially if it is possible identify the forms which they have found with two well-known colony variants formerly descri by Cobbett and by Sclawyk and Manacatide, who not find any change in virulence in their variants with the "non-virulent" variant with a spe colony form recently obtained by M. Cowan Maitl from several virulent strains. In these researc the authors procured the variants pari passu w the more normal forms from virulent cultures.

is not quite clear whether the S and R forms, n Commanders Dudley and Parker found to be asted in toxigenicity, were from different sources ere both derived in each instance from a single n. In the former case the reasons for believing they were all *C. diphtheriæ* are required to lete the evidence. Definition of a species in ria is difficult as Commander Dudley admits, he assignment to *C. diphtheriæ* of a culture which ither toxigenic nor descended from a toxigenic n is a difficult and often unconvincing task.

e study of variation in bacteria is not yet very dvanced, but definite variation in antigenic ituents has already been described in several nces and found related to more obvious changes aracter. There is also good evidence that anti- composition may be closely connected with factor in the composite character known as nce. This is notably the case in the factors n have been studied both chemically and gically by Avery, Heidelberger, and others—e.g., e pneumococcus. It therefore seems probable even in so variable a group as the bacteria ble evidence of orderly variation will further mulate and prove to be of wide theoretical and ical value.

I am, Sir, yours faithfully,

JOSEPH A. ARKWRIGHT.

er Institute, S.W., August 7th, 1928.

E HEREDITARY AND CONSTITUTIONAL FACTOR IN ADDISON'S (PERNICIOUS) ANÆMIA.

To the Editor of THE LANCET.

S,—In your annotation last week on the tinal Bacteria in Pernicious Anæmia you state the evidence for an hereditary or constiutional nt in the disease is "rather nebulous." In a e published in THE LANCET five years ago I ht forward what I regarded as conclusive nce in favour of such an hereditary or constinal element. I believe this conception is of mental importance in the pathogenesis, prophyand treatment not only of Addison's anæmia), but also of the associated nervous disease—ute combined degeneration of the spinal cord D.). I should like once again to summarise idence on the subject, as many further observabearing on it have been made since the publicaf my lecture.

absence of hydrochloric acid from the gastric ion appears to be the one essential predisposing of the two allied diseases. It is most frequently o constitutional achylia gastrica, an inborn of secretion, which is strictly comparable with d's inborn errors of metabolism, such as cystina alkaptonuria, and pentosuria. The error is f function and not of structure, as the mucous rane is normal and has a normal number of ic cells. Achylia was present in 4 out of healthy students examined by Bennett and t Guy's Hopsital; it occurs in early childhood, often present in several members of a family. ez has observed more than 20 such families, of which a great-grandmother, her daughter, randchildren, and five out of 13 great-grandn had achylia. I have had under my own brother and sister and two sisters with digestive oms caused by achylia gastrica.

familial occurrence of achylia gastrica must explanation of the familial occurrence of A.A. has been recorded by many observers. I have ed no less than 62 family histories from the ure, and 7 out of a series of 25 cases at New Clinic (27 per cent.) had one or more relations ad died of the disease.

elt records the case of a mother and daughter f whom suffered from S.C.D., and of a father and son with the disease, the grandfather having died of A.A. Willson, in 1912, described the case of a woman with S.C.D., two of whose maternal aunts had died of A.A. I have set with a similar family history in 4 out of 16 private patients with the disease: the mother of one and the paternal grandfather of another died of A.A. The most remarkable case was that of a doctor who died of S.C.D. associated with achylia gastrica and A.A.; his brother, father, paternal uncle, and paternal grandfather had all died of A.A. The brother of another doctor with severe A.A. and slight S.C.D. was found to have S.C.D. and achylia, but perfectly normal blood.

Five patients, who have consulted me for various conditions associated with achlorhydria, had one or more relatives who had died of A.A. I have collected records of 28 other cases in which A.A. in one or more members of a family was associated with achylia in others. The brother of a doctor of 42, who consulted me for digestive symptoms due to achlorhydria, had died at the age of 41 after being ill for 18 months with S.C.D. and terminal severe anæmia, and Evans has described the case of a man with S.C.D. and achlorhydria but no anæmia who had a sister with achlorhydria. Dorst has described a family, different members of which had either A.A. or S.C.D., or achlorhydria without nervous symptoms or anæmia.

A woman of 50, who was feeling quite well except for occasional diarrhœa and eczema, sought my advice mainly because she had become worried about herself owing to the number of relations on both sides of her family who had died of Addison's anæmia. Her sister, paternal grandmother, and a cousin of her father's had died of it, a paternal cousin of her own had it now, and her mother died of it. Her tongue, which had been sore from time to time for three years, had the characteristic appearance of Hunterian glossitis. Her hæmoglobin percentage was 76 with 4,100,000 red corpuscles per c.mm., and the average size of the red corpuscles was increased from the normal of 7·23 μ to 8·34 μ, but the red cells were otherwise perfectly normal in appearance. She had complete achlorhydria.

In connexion with the bacteriology of Addison's anæmia I regret that you make no reference to the important observations of Knott on the subject, most of which have been published in the Guy's Hospital Reports, as the more recent investigations of Dr. Stanley Davidson, which form the basis of your annotation, do little more than confirm his pioneer work.—I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, August 6th, 1928.

INSTRUCTION IN PSYCHIATRY.

To the Editor of THE LANCET.

SIR,—Your review of Dr. H. J. Norman's book on Mental Disorders (July 21st, p. 125) will be approved by many of the older school of psychiatry. Yet it is disconcerting to find approval of a book, intended for students, on the ground that it does not deal with modern psychopathology. The most elementary knowledge of mental processes is withheld from our students. The metaphysical nature of the effort to correlate disordered conduct with disordered neurones, and its entire failure and practical futility in the psychoneuroses, are concealed from them. The mental attitude thus induced often persists throughout professional life in people of a certain temperament. Others make the discovery that something is wrong with their education or philosophy and feel helpless when faced with the many psychoneuroses of general practice, with only their traditional training in "neurones" to fall back upon. I am often asked by practitioners where they can learn about these matters, and where they can meet others of similar inclination to discuss their clinical difficulties and find out what is to be learnt from modern psychopathology. For this reason I ask the indulgence of your columns to notify that an effort is being made to form a small

society with these aims and I shall be pleased to hear from any would-be supporters.

I am, Sir, yours faithfully,

Harley-street, W., July 24th, 1928. ESTELLE COLE.

*** Dr. Cole raises a very important point, but our reviewer has not exactly approved the absence of teaching in psychopathology so much as conveyed the opinion that so important and difficult a subject should be properly taught or left alone. We have seen instructions in manuals of psychiatry which could have but little relation to the counsels which would be given by lectures to students out of first-hand experience.—ED. L.

CANCER AND THE BLOOD-GROUPS.

To the Editor of THE LANCET.

SIR,—In general practice there are occasions in which cancer appears to be a family disease, and on the other hand, some family strains appear to be immune. If not already dealt with and known, an investigation of the relative incidence of cancer in the different blood-groups might prove interesting.

I am, Sir, yours faithfully,

PENROSE WILLIAMS, F.R.C.S. Edin.

Cornwall, August 6th, 1928.

HOME PRODUCTION OF COCAINE.

To the Editor of THE LANCET.

SIR,—In an annotation entitled The Traffic in Narcotic Drugs, which appeared in your last issue (p. 236), you refer to the manufacture of cocaine in this country and state that hitherto there has been no production of cocaine from the leaves, or by refining crude cocaine, in Great Britain, adding that in 1927 a licence was granted to a firm of manufacturing chemists to carry on experiments in such manufacture. You will be interested to learn that cocaine was manufactured by us in 1903 at the Wellcome Chemical Works, Dartford. We were granted a Home Office licence in March, 1917, and have manufactured many thousands of ounces of cocaine at Dartford.

We are, Sir, yours faithfully,

BURROUGHS WELLCOME AND CO.

Snow-hill-buildings, London, E.C.,
August 8th, 1928.

SMOKE ABATEMENT INQUIRY AT BRADFORD.—Mr. F. O. Sandford, of the Ministry of Health, recently conducted an inquiry at Bradford into the application by various West Riding authorities for new by-laws on the smoke nuisance. The proposed by-laws provide that the emission of black smoke for two minutes in the aggregate within any continuous period of 30 minutes should constitute a nuisance. The authorities applying for the by-laws were Bradford, Huddersfield, Leeds, Halifax, Dewsbury, Batley, Spenborough, and Guiseley. In support of the application it was stated that the decision to apply for new by-laws arose out of a recommendation by a regional smoke abatement committee for the West Riding of Yorkshire, which represented something like 100 local authorities and a million people, and that committee approved of the terms of the suggested by-laws. In Bradford alone there were 438 industrial chimneys and 1330 furnaces. During the last seven years there had been 73 proved cases of smoke offences, and one firm had been prosecuted 70 times. The standard adopted in regard to smoke nuisance varied widely in the districts concerned. Amongst others evidence in support of the application was given by the medical officers of Bradford and Leeds. In opposition to the proposed by-laws by various trade associations and chambers of commerce it was stated that it had been proved by experience by firms with the most modern plant that it was impossible to comply with the terms of the by-laws. It could not be worked in practice, except by imposing a tremendous burden on industry. It was contended that the existing local Acts in Bradford were quite sufficient to deal with the problem.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

PROROGATION OF PARLIAMENT.

PARLIAMENT was prorogued on Friday, August 3rd, Tuesday, Nov. 6th. The Royal Assent was given by Commission to a large number of Acts passed during past session.

HEALTH ADMINISTRATION IN SCOTLAND.

On Tuesday, July 31st, the House of Commons went Committee of Supply on a vote of £2,037,515 for the sa and expenses of the Scottish Board of Health. Mr. J HOPE was in the chair.

Mr. W. ADAMSON said the subject he wished to rais the deterioration of the physical condition of the Sc people due to the inadequate provision that was being for them by the Scottish Board of Health. There w number of causes that were leading to the poverty-str conditions in which a large number of Scottish people themselves to-day, but the main cause was unemploy That problem was even more severe in Scotland than in England. Nearly one-third fewer miners were employed to-day than were at work in 1924. In many the unemployed persons had been out of work for a siderable time. In Glasgow the period of unemploy ranged from six months to six years. This problem bearing very heavily upon the local authorities in Scot and particularly upon the parish councils. He wish impress upon the Secretary for Scotland that the prov made in these estimates to deal with the problem of po and distress in Scotland were quite inadequate. In last estimates they had £260,000 in grants made to councils in respect of poor relief, but this year there wa a single penny. He appealed to the Secretary for Sco to examine this problem closely with a view to more done by the Scottish Board of Health to enable Scotla shoulder this grievous burden.

Dr. DRUMMOND SHIELS said that that was the last they would discuss the report as the report of the Sc Board of Health. In the valedictory foreword whic members of the Board had inserted in the report expressed the belief that the efficiency of the work department in future would not be inferior in any w that of the Board. Although Labour Members had str opposed the change that was to be made they sin wished that the high standard of efficiency associated the Board of Health would be maintained under th régime. He wished to know what was the position regard to the vacancy in the medical membership Board. It was known for a long while in advance th Leslie Mackenzie was going to resign. Could the Sec for Scotland now intimate who his successor would He sincerely hoped that when the appointment was it would be found that a member of the present sta been promoted to the position.

Milk-supply and Tuberculosis.

The question of the milk-supply and tuberculosis w said, dealt with in the report. Undoubtedly unde effective administration of Dr. Leighton a very great im ment had taken place in the milk-supply of Scotlan was much cleaner and better than it had ever been. had been a gratifying increase in the quantity of li graded milk, but it still amounted to little more t per cent. of the whole milk used in Scotland. The n clature of the grades was very misleading. There w doubt that Grade A in bulk, which was only the third qualities, was considered by many people to be th quality, while the tuberculin-tested milk had not proper position in the public mind because of confus Grade A milk with that of the highest quality. revision of that nomenclature ought to be made, so th public could understand properly what the position He would like to know if the Secretary for Scotlan satisfied with regard to pasteurised milk? If pasteur was carried out effectively this milk was safe, but there great liability for pasteurisation to be done ineffec and to be a danger rather than a help by misleading as to its safety. The report did not deal with the Was any definite standard laid down; if so, was it enforced; and had there been any cases where pasteuri which was becoming almost the most popular fo protecting milk, was regarded by the Department as wholly safe and to be trusted?

The report stated that last year 2240 animals, cows, were condemned as tuberculous, compared wit

926. The Board of Health considered that the increased ber was a sign of increased efficiency in the inspectorate, if that was so, he was glad, but it also showed that e was still a substantial amount of tuberculosis among le in Scotland. In view of the danger to young children, cially the poorest, it was well that effective steps should aken to deal with the matter. Even the Empire Market-Board were now publishing placards inviting people to more milk, but in view of the fact that the former entage of tuberculous milk was 8 per cent., he would state to recommend anyone with young children to use nary milk unless he was satisfied—which he was not—that percentage had been reduced almost to vanishing t. It would be a good thing if the right hon. gentleman d reassure the public mind as to the quality of the milk, iew of the propaganda that was being carried on for ased consumption. The report contained a chapter on real disease. What was the position of the department gard to that subject? The chapter in the report was very iously written, but it showed that the technical heads of department were not at all satisfied with the position. large sum of £60,000 or £70,000 was being spent in land alone in dealing with this disease, and something £600,000 throughout the Kingdom. Yet in Scotland percentage of defaulters was 51. That showed an alling waste of public money. The local authorities cotland were of opinion that the present arrangements not satisfactory or efficient.

Coöperation Between Hospitals.

he question of coöperation between hospitals was being carefully considered by many bodies, both in England Scotland. The voluntary hospital managers were very h concerned at the present position, and the question coöperation between the voluntary, municipal, and poor-hospitals was bound to arise in connexion with the posed local government changes. In Aberdeen there was arrangement that seemed to be very desirable. The sh councils there had handed their hospitals over to the lic Health Committee of the town council, and the whole e public health accommodation there was being adminis-d by one authority. In Glasgow, also, there was a king arrangement of a similar kind. Many of the poor-hospitals in Scotland were not well equipped or quately staffed, and the association, with the municipal ices, and with the staffs of the various voluntary hospitals, bound to improve their efficiency. He was glad that Department seemed inclined to encourage that. He ld like to ask if the Secretary for Scotland had any rmation to give in regard to Craigleith Hospital. The ction of that institution and Craiglockhart Hospital, nderstood, was being considered and, in view of the tage of beds in Edinburgh Infirmary, it would be as if some arrangement of that kind were made as soon possible. The report of the Mackenzie Committee ed that there was a shortage of 3600 beds in Scotland years ago, and the position was not any better to-day. the Minister consider that adequate arrangements now been made, or were likely to be made, to provide n early date a proper number of beds? The Scottish mittee of the British Hospitals Association had set five local committees for coördinating the various ital activities, and there was also a liaison committee een those bodies and the Department. Why were e no representatives of the municipalities on that on committee? This ought not to be a matter purely een the managers of voluntary hospitals and the artment; the municipal medical services ought to be esented in any working arrangement of this kind, use there was in these negotiations a danger of magni-g to too great an extent the importance of the voluntary ciple and to say that it must be preserved at all costs. first consideration must be the efficiency of the hospital ice and the supply of an adequate number of beds. le they acknowledged the important work which the ntary hospitals had done, they regarded the voluntary t as being the pioneer, and considered that when the ssity of the work was evident it should be done by the ic authority, so that adequate medical attention might iven to all classes of the community.

hat had happened to the report of the Departmental mittee on Maternal Mortality which was issued about nonths ago? How many of its recommendations had put into operation? There was no doubt that this ect must ultimately be dealt with by municipal maternity ices, and by ensuring coöperation between doctors midwives, and between the ante-natal services and other public health services. He could not now go the large question of the nutrition of school-children, he called attention to the fact that last year 6·4 per . of school-children in Scotland were in a state of ition below the average, while 1·5 per 1000 were in a state of very poor nutrition. Was the Board of Health urging local authorities to put into operation the whole of their powers for feeding necessitous children? With all the poverty and misfortune in Scotland there was money enough to feed the children. The same consideration applied to the questions of the dental treatment of school children and treatment of adenoids, tonsils, and so on. There was no doubt that many of these children were suffering in health because of defects which, if their parents were in a better position in society and had more money, would be remedied as a matter of course; but because the parents were unable to afford it, and because the school medical service was not big enough and had not sufficient resources, they were left to drift very often into a state of chronic ill-health.

Mr. MACQUISTEN attributed the poverty of some districts of Southern Scotland to Irish incursion.

Mr. JAMES STEWART drew attention to the alarming figures in the report with reference to tuberculosis, both case-rate and death-rate being on the ascendant, especially in the Highlands and Islands.

Mr. T. HENDERSON called attention to the inadequacy of the efforts to suppress venereal disease in Scotland.

Reply to the Debate.

Major ELLIOT (Under-Secretary of State for Scotland) in replying to the debate, said that the Board of Health were keeping an anxious watch on the health of Scotland to see if deterioration was taking place—that deterioration which indeed one would expect from the long-continued industrial depression. They had not yet any evidence to lead to the conclusion that deterioration was taking place. The reports of medical officers of health on the school population did not indicate any deterioration in the health of the children of Scotland generally. They had kept a watchful eye on the vital statistics of the country. It was true that last year the pulmonary tuberculosis figures were higher than those of the year before, but they were lower than they had been for any year up to that time, lower than in 1921, 1922, 1923, 1924, and 1925. Non-pulmonary tuberculosis continued to fall and was lower last year than ever before. They all agreed as to the tremendous struggle through which industrial Scotland was passing and the Government were not blind to the situation. They recognised the urgent necessity to deal with it by legislation which would be laid before the House before the end of the present year. Dr. Shiels had said that the percentage of underfed and badly-fed children was too high and he (Major Elliot) agreed with him. They must continue to do their utmost by improving the school medical services and by tightening up regulations to make sure that the Education Act was carried out and that every child got sufficient nourishment to enable it to take advantage of education. There was no divergence of opinion between the Secretary of State and his advisers on the question of venereal disease. The report made it quite clear that in the opinion of the Secretary of State the time had not come to ask the House for further compulsory powers until they were sure that the powers already entrusted to the local authorities by the Government had been utilised to the full.

Dr. SHIELS said that the point he wished to make was that there was a divergence of opinion between the Scottish Board of Health and the English Ministry of Health and not between the Secretary for Scotland and his advisers.

Major ELLIOT said he could assure the hon. gentleman that the Secretary for Scotland was in no way inclined to defer to the opinion of the English Minister. He considered the matter on its merits in consultation with his technical advisers and in accordance with their advice he came to the conclusion mentioned in the report. The Scottish Board of Health were not flinching from drastic action to make sure that the milk-supplies were as pure as could reasonably be managed. In reply to Dr. Shiels's question as to the medical member of the Board of Health, everyone knew that Sir Leslie Mackenzie had now retired, and it was right that Parliament should take note of that fact and remember, with gratitude, the great work that he had done for the health of the people of Scotland—(general cheers)—during the many years that he had been entrusted with that duty. The reason that a new medical member had not yet been appointed to take his place was simply that the Bill for the Reorganisation of Offices in Scotland had not yet received the Royal Assent. As soon as that Bill became an Act of Parliament the Secretary for Scotland would proceed with the utmost expedition to make the new appointment. He had nothing further to report for the moment in regard to hospitals, but the proposals that Dr. Shiels had brought forward would be considered. He was not able to say that the shortage of hospital beds had been remedied, but an improvement was being effected almost monthly, with the provision of increased

hospital accommodation for the sick people of Scotland. Only a few weeks ago he had opened the new Northern Infirmary at Inverness where considerably increased medical facilities had been made available for the people in the northern districts. With regard to the report of the Departmental Committee on Maternal Mortality, the Board had done their utmost to bring up to date the system in Scotland in regard to the services for pregnant women. The Maternity Homes Act ensured that there was now a service available for 100 per cent. of the mothers of Scotland, a thing that could be said of very few other countries in the world. The Board had not succeeded in reducing the very high percentage of deaths from puerperal fever, but they were considering fresh steps for dealing with that matter. The service had been made available, however, and they would do their utmost, by administrative action, to secure that further institutional accommodation was made available for women in childbirth. In regard to tuberculosis there were fluctuations from year to year, but what they had to observe was the general trend of the figures and that gave them no reason to despair or to feel that any serious inroads were being made on the health of the people of Scotland. As regarded tuberculosis in the Island of Lewis they had done their utmost to deal with that matter. Sanatoria had been opened and there were three whole-time men and three medical officers of health and assistants working part time on that problem. It might be that they were dealing there with a hereditary resistance which was lower than the resistance on the mainland, or in those parts of the country which had been longer exposed to the infection of the disease. They were, however, at present engaged in investigations to see whether that was the case or not. The nine years during which the Scottish Board of Health had presided over public health matters in Scotland had been years of varying fortunes, but as regarded health, housing, and social conditions they showed a distinct improvement. If they could make as much progress in the next nine years he would be satisfied.

Mr. JOHNSTON asked if the Under-Secretary could make some statement with reference to the practice carried on for some considerable time by one firm of importing inedible grease by the shipload from abroad and selling it to poor people as edible lard?

Major ELLIOT said that the Government took a serious and grave view of this matter. They felt that a definite offence had been going on. The local authorities upon whom the onus of prosecution fell had now the matter under consideration. The Government would not stand in the way of steps being taken, if they desired to take steps. The stock now under embargo in Glasgow would be dealt with as the order of the Court decided.

The vote was agreed to.

MINISTRY OF HEALTH VOTE.

On Wednesday, August 1st, the House considered the Report of a vote of £13,774,025 for the salaries and expenses of the Ministry of Health.

Mr. LANSBURY protested against the reduction which he said the Minister of Health was making in the grants for milk distribution, housing, and slum clearance, and poor-law relief.

Lieut.-Colonel FREMANTLE said that there had been presented to Parliament in the last two days a report from the Departmental Committee on Vaccination, which could not be taken into account so late in the session, but which must be referred to. Having enumerated the circumstances which led to the appointment of the Committee—certain objections to the practice of vaccination and certain doubts with regard to the necessity of its continuation on the present lines owing to the milder type of small-pox—he called attention to the danger represented by the large number of unvaccinated people which was increasing every year in proportion to the whole population, a circumstance which had an international aspect, because other countries held that vaccination was a very small price to pay for protection from a very alarming disease. Therefore action was required to be taken, and in the first instance a scientific committee was appointed to inquire into the nature of vaccination and into the various conditions which appertained to the operation of vaccination. That committee had presented a lengthy report which, from a scientific point of view, did great credit to its authors, and left the legislators very much in the same position as they were in originally from a practical point of view, for it showed that the position required further investigation on scientific lines.

Vaccination and Nervous Disorder.

There was one point which the report raised—it had been made a serious problem in the Press as well as in the House of Commons—and that was the occurrence in the period after vaccination of certain unfortu cases of nervous disorder which had been stated some hastily, and by others anxiously, as being poss due to the operation of vaccination. This report c with those cases very thoroughly. They had to t these exceptions in their proper light and proport and the report showed that they were a small nun compared with the total number of vaccinations. total number of cases with which the Committee c was 62, of which, unfortunately, a considerable nur were fatal. They must recognise the seriousness of t facts; but when they were dealing with 314,000 prin vaccinations in one year 62 in all was a small number they must not exaggerate its significance. The t number of deaths from vaccinia over a period of years had only been 0·001 per 100 vaccinations. Still, t were facts which have to be faced and they who were keen supporters of vaccination as essential to the commu would be misleading the House if they did not face th The report showed first of all that it was a curious t that in the year 1924 the Committee could trace no c whatever, although they searched most diligently thr all the records of the results of vaccination, and t records were very complete. The Committee found s of these cases in 1922 and 1923. They found a close ass tion between these cases and the epidemics of disease kn as encephalitis lethargica and poliomyelitis. The clusion that the Committee came to was that just as chil suffering from scarlet fever, measles, and other ordi ailments were more susceptible in a time of outbrea poliomyelitis, so similarly those who had been vaccin were liable to be attacked by these passing diseases time of epidemic. The Committee pointed out exa the limits within which further observation was requ the points to which their sense of anxiety must be dire and the directions in which in future they hoped to be ab find out exactly the nature of the trouble which had ca this symptom, which was entirely accidental both graphically—for it had occurred in Holland as well a this country—and in years, and they might hope that would not see them occur again.

The speaker looked forward to the improvemen vaccination administration that would follow its t ference to the sanitary authorities, and deplored the con of those who, in defiance of the facts, tried to terr people on lines which every man who was sensible beli were scandalous exaggeration and malicious inventio

Ministry of Health Estimates.

He would like to look shortly at the total estimat the Ministry of Health. The total estimate for this was £20,000,000, showing an increase of nearly £1,00 on last year, for excellent reasons. Of the £20,00 over half was due to housing, so that the public h side was under £10,000,000. The prevention of di which was preventable had resulted, and was resultin an enormous improvement in the health and effici of the people as well as in their general habits. But estimates for the Defence Forces amounted to £114,000 The real moral of the contrast between that large sum the £10,000,000 spent on the prevention and cure of di was that when there was a clear case made out for expenditure for the Ministry of Health there should l question raised about it. If they could get general a ment on this on very side of the House he would su to those who, like himself, were keen on the preventi disease and on improving the lot of suffering huma that they should be very careful what they supported careful to avoid waste. There had been cases again again where extra money has been asked really as an dole and not for the prevention of disease. They de further provision to be made for the clearance of the sl They must focus attention in the provision of housin the very poor, and in order to do that it would be the of the State before long to remove the subsidy fro upper grades of houses, because the people who liv those houses could look after themselves now.

Housing and Health Services.

Mr. HARRIS said the money which had been spe housing and health services was most important, a was more impressive when they remembered the imn improvement in public health during the last 15 or 20 y largely due to schemes undertaken for that purpose. various schemes which were initiated by the Govern before the war had borne excellent fruit, and had justifie expenditure. In some boroughs, even in very cro areas, the system of maternity and child welfare had l remarkable effect on the death-rate. For instanc Bethnal Green, the poorest neighbourhood in the wh London, and the most overcrowded, they had reduce infantile mortality to 57·7 per 1000. In that respect

been able to take the prize for the best result in London. t figure compared with 59 per 1000 for London as a ole, and 69 per 1000 for England and Wales, including rural and well-to-do districts. Their infant death- had shown a steady decline. In 1916 it was 106 per 0. In 1918 129 per 1000. It then came down to 90 922, next to 71, and this year it was 57. That reflected y great credit on the medical officer and the loyal servants worked with him. It was not unreasonable to say t this improvement was largely due to the distribution free milk. There had never been a better expenditure public money than the giving away of milk through the lth departments of the local authorities. In Bethnal en milk was given to expectant mothers three months re confinement, to nursing mothers, and to children to 3 years. One pint per day was given, and that was enough to demoralise any woman or any child. Except children between 3 months and 18 months no larger ntity was given; it was then at the maximum of 1½ ts, and in that case a medical certificate was required. could not make out why the Minister of Health had led out this expenditure on milk for his special veto. now said that milk should not be given away to mothers their children who were in receipt of poor-law relief, ctly or indirectly. He required a special medical ification before even a pint of milk could be obtained. t was most unfortunate. It might be said why should these people buy the milk themselves? Unfortunately k was not a popular diet; and they had to do a great l of education in that direction. The Empire Marketing rd was spending thousands of pounds in putting up ters urging people to drink more milk. Not only was distribution of milk valuable from an educational nt of view, but it was most important at this very sensitive ge of a child's life.

Tuberculosis.

he complex problem of tuberculosis had racked the d of every Minister of Health and of every local authority. medical officer of health in Bethnal Green had given nt attention to the subject. In connexion with the th-rate from tuberculosis a very serious phase had been ated out to him. There had been a very heavy and rapid tality among patients who had died within a year of ification. In 1917 the percentage of patients dying hin a year of notification in Bethnal Green was 21·9, and 1922 the percentage was 26·9. They had taken the ble to follow up the cases. The reason for this alarming th-rate had been given to him by their very able medical er as due to the diffidence among patients in informing authorities that they were suffering from the disease. onference of local authorities in London had pointed he great success of the experiment at Papworth, where strial training was correlated with treatment. The ister of Health might well spend a little time inquiring that matter, and take steps to encourage those suffering the disease to notify the authorities earlier. All these th questions were, however, connected with the housing blem. One of the difficulties in dealing with tubercu- s was that when a man returned nearly cured, he had o back to a two- or three-roomed tenement, and share house with a family of five or six children. He was not g to underrate what the Ministry of Health or the local orities had done, but there was a little danger in the mism which said that most of the lee-way had now been e up. Whatever the Minister might do in the way of cing the subsidy on the more expensive houses, he t on no account consider for a moment reducing the idy on houses which were wanted to meet the real urgent need of the working classes.

aptain BOURNE said that there were on the registers of t authorities some 363,000 people suffering from tubercu- , and of that number some 63,000 were treated in any year in sanatoria. The average stay of a man in a sana- m was some 150 days, and the cost per patient was 3½*d.* per week. That meant that the total cost of toria treatment was between £4,000,000 and £5,000,000 annum. If it were certain that that sum would really t the cure of tuberculosis, he did not think anyone d grudge the money, but the Minister, when he was d if he had statistics to show how many of the people passed through sanatoria were cured had to admit he had no reliable information on that subject. There been in his constituency recently an effort to deal with of these cases by means of the tuberculin treatment. le that method had been reported upon unfavourably, d nevertheless been tried in some localities with very ficial results. The tuberculin treatment had one ntage. It did not require isolation in a sanatorium, a man who was undergoing it could go about his ordinary pation. It was a very much cheaper form of treatment sanatorium treatment, and although he spoke with diffidence as a layman, he felt that anything which might possibly be helpful to people suffering from this disease ought to be investigated by the Ministry.

Mr. BRIANT raised the question of the conditions in the hop districts. He said that having seen these conditions for himself, and having studied the reports of the medical officers dealing with them, he did not hesitate to say that in a large part of these areas the conditions were absolutely disgusting and unfit for any human being.

Colonel APPLIN asked if the Committee on Maternal Mortality had reported, and if so, what was the nature of the report? Were they going on in the same old way allowing mothers to die when their lives might be saved? When the Committee had reported would the Minister consider giving the same information to the poor women as was given by private doctors to those who were better off? As long as that information was withheld, they would have this great mortality among mothers, and go on rearing a generation of young people unfit to come into the world by reason of their mothers being unfit to bear them.

The Welsh Board of Health.

Mr. JOHN protested against the Minister's action in reorganising the Welsh Board of Health. Under the new scheme he said they were to have no Board of Health in Wales, but instead they were to have three officers in Cardiff carrying out the work of civil servants under the direct instructions of Whitehall, with no provision whatever for joint action under a duly appointed chairman.

Mr. LLOYD GEORGE said he very much regretted that it should have been necessary to raise this question at all in the House. He had hoped after the representations made to the Minister, not merely by his political opponents but by the whole of his political friends in Wales, that he would have made this concession to the unanimous wish of the Welsh people without distinction of party or creed. He urged the Minister of Health to reconsider this matter.

The Minister's Reply.

Mr. CHAMBERLAIN (Minister of Health) said the Welsh Board of Health had never been a board in the ordinary sense of the word, because a board in the ordinary sense was an executive body, and the Welsh Board of Health had never been an executive body since it was set up. The Welsh Board had never had the powers of the Scottish Board of Health. This was purely an administrative matter. As to the question of economy, when he decided for reasons which appeared to him sufficient and satisfactory, that he could not appoint any existing member of the Board to be chairman, he had to consider whether he should bring in somebody else. The work of the Board of Health had not been executive, and it had found so little to do that on the average it had met only three times a year during the last nine years. All its work had been done by its members in their individual capacity. It had been extremely efficiently done, and he had not heard any complaints about it. To bring in a chairman, who would really have no functions, at a cost of £1600 a year would be a course in which he would not be justified. It was not his desire to bring into publicity anything in the nature of a reflection upon any member of the staff in Wales. He thought it necessary, in receiving the deputation on the subject, to say something about it, and he thought that they would consider it as a private matter between themselves and himself, but since it had been made public he would say here was a case, not of any dishonourable action on the part of anybody, but of a series of petty personal squabbles that had taken place in the office. He had disciplined and censured those who had been guilty of subordinating the public interest to their own personal prejudices and feelings. The matter was settled, but to put one of those who had been concerned in these internal differences into a position in which he could or might affect the promotion of others with whom the differences had arisen, did not seem to him a step which he could possibly take in the interest of the administration of public health.

Poor-law Relief.

Dealing with the question of poor-law relief, Mr. Chamberlain said they had not found any cases of starvation. There were many cases of hardship, but if it was really to be laid down by the Labour Party that those who were unable to support themselves were to be supported by the State on the same scale as those in full work, he said that it could not possibly be done. Complaint had been made about the reduction of the grant for milk. He much regretted that it should be necessary to make any reduction, but they had to bear in mind that the practice of local authorities as regarded the amount of milk given varied enormously. Some gave nothing at all, and in other areas he expenditure was up as much as £20 per 1000 of the population. All authorities could not be equally right in

this matter. They had not laid down in a single case that this special form of assistance to nursing and expectant mothers was to be stopped. They had not forbidden any local authority to give milk or to give as much milk as it chose; all they had said was that they must limit the amount of the Exchequer grant, and the reduction was comparatively small. It was not a matter of policy on the part of the Ministry to reduce the amount of milk; if it had not been for economy he would not have done anything at all, but he would not like to admit that this economy was going to undo the work that had been done in the past in the preservation of infant life. What had happened was that having stated that the Exchequer grant in certain cases would have to be reduced, he had made certain suggestions which the local authorities could adopt if they desired to reduce their expenditure with the least possible disturbance to their existing practice.

Health Conditions in the Hop Fields; Sanatorium Treatment.

With regard to the hop fields the Ministry of Health had very little power beyond that of exhortation. What they needed in this matter was the education of public opinion. No doubt the conditions in the hop fields were very far from being what they should be, and he had done what he could to induce local authorities to adopt model by-laws, and to see that they were carried out. In the absence of further powers it was not possible for him to do more. Conditions were improving, though he agreed that there was much to be done. Captain Bourne had expressed some doubt as to whether they could be satisfied that the money spent on sanatorium treatment was justified by the results. They had not got figures from sanatoria all over the country which would show exactly what happened to people after they had been discharged, but some time ago they got from the Brompton Hospital Sanatorium particulars of between 3000 and 4000 patients who had been discharged. They showed in regard to the moderately advanced cases that after five years 57 per cent. of the males and 67 per cent. of the females were not only alive but apparently in good health; and that after ten years 38 per cent. of the males and nearly 50 per cent. of the females were also alive, and as far as he knew, in good health. That reassuring statement indicated that the money spent upon sanatoria was well spent; it prolonged the life of many people, and saved the lives of a good many others, and even where it was not able to do this, it did much to diminish the infection which otherwise might take place among the healthy population. In regard to housing, it was quite true that the progress made under the Rural Housing Act up to March, 1928, had been singularly disappointing, but in the three months since then progress had been very much faster. The number of dwellings in respect of which applications for assistance had been received, which was 1072 up to March, 1928, had increased to 1500 in the succeeding three months. In regard to housing in general, month after month not only the number of houses completed continued to go up, but also the number of houses under construction; and that number, which was only 48,000 last January, was to-day 59,000. He would be very much surprised if they did not get another 100,000 houses before the end of this year.

The vote was agreed to by 255 votes to 132.

THE LATE DR. HEYWOOD SMITH.—At the age of 90, Dr. Heywood Smith died at Chichester on July 25th. The son of Dr. Protheroe Smith, founder of the Hospital for Women, Soho-square, he was educated at Harrow and Christ Church, Oxford. His clinical training was obtained at St. George's Hospital, and on graduating in 1865 he held a house appointment there before taking up gynæcology as a specialty. He became M.R.C.P. Lond. in 1865, and proceeded to the M.D. degree at Oxford in 1870. Seven years later he published "Practical Gynæcology, a Handbook of the Diseases of Women," based on his experience on the staff of the British Lying-in Hospital and the Soho-square Hospital, to both of which he subsequently became senior physician. Other books and scientific writings followed, and Heywood Smith was one of the founders, and some years later president, of the British Gynæcological Society. On retirement from consultant practice in London he went to live at Hove, where he was living at the outbreak of the late war. Joining a veteran's corps, he was given medical charge of an air-raid station, and later did good work as civil medical officer to the Military Hospital at Chichester, where he finally established himself in retirement.

Dr. Heywood Smith, who was twice married, leaves a widow, two sons who are members of the medical profession, and a married daughter.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation h on August 4th the degree of Bachelor of Medicine conferred on T. L. Davies and A. J. Leslie-Spinks.

UNIVERSITY OF CAMBRIDGE.—Applications invited for the Benn W. Levy Research Studentship, val at £100 a year. They should be sent to Sir Gowl Hopkins at the Biochemical Department before August 14

ROYAL COLLEGE OF SURGEONS OF ENGLAND. At a meeting of the Council held on July 31st, Sir Berke Moynihan, the President, in the chair, diplomas of M.R.C were conferred upon 158 candidates (130 men and women) who have passed the requisite examinations a have complied with the by-laws of the College. Th candidates are the same as those whose names were print on p. 259 of our last issue, except that Nellie Brown (We minster), David W. Currie (Leeds), Yatta Gimpelson (Ro Free and St. Mary's), Ralph H. Morley (Leeds), Bhava Natarajan (Bombay), H. G. Nimbalker (Bombay a Middlesex), Margaret E. Peaker (King's Coll.), Edith J. Smith (Royal Free), G. N. Unnithan (Madras and Un Coll.), and Elsie E. Wright (Royal Free and St. Mary received their diplomas of Member at a previous meeti of the Royal College of Surgeons, and Thelma Sheph (Royal Free) received her licence from the Royal Coll of Physicians on July 31st.

The Diploma of F.R.C.S. was conferred upon Herb John Seddon (St. Bart.'s), who has passed the requis examinations and has now attained the required age.

Licences in Dental Surgery were also conferred up A. M. Bennett and H. A. Lewis, both of the Royal Den Hospital.

Diploma in Tropical Medicine and Hygiene.—This diplo was conferred (jointly with the Royal College of Physicia upon the following 33 candidates who have passed requisite examinations:—

T. D. Amad, Maud C. Cairney, K. Cathiravelu, G. L. Chad S. S. Crosse, C. H. Devereux, J. P. M. Donnelly, N. Dotivala, Alice M. A. Downing, A. W. Duncan, H. A. Gill M. A. E. Gohar, I. S. Gupta, N. Gupta, M. Jafar, H. Johnson, H. Kaitz, Mary Keith-Thompson, J. N. Leit K. R. Lundeberg, L. J. McGregor, C. D. Newman, Annie Price, E. L. Robert, A. N. Sharma, G. Singh, J. D. S. Thom R. F. Tredre, M. K. Tucker, K. H. Uttley, Kathleen Vernon, P. L. Whig, and E. R. Wide.

ROYAL COLLEGES OF PHYSICIANS OF LOND AND SURGEONS OF ENGLAND.—As the result of the Fi Examination of the Conjoint Board held in July, following candidates were approved in the undermentio subjects, but are not eligible for diplomas:—

Medicine.—S. Alstead, Liverpool; S. Annaswami, Madras London; Nancy M. Badeley, Royal Free; S. W. Barl St. Bart.'s; F. E. Camps, Guy's; Rochelle Churin, Rc Free; C. F. Cosin, Guy's; W. W. Craner, London; T. Crichlow, King's Coll.; H. W. D. Crook, Guy's; S. Crowther, Cardiff; T. M. Davie, Middlesex; E. Edmondson, Cambridge and London; C. N. Evans, Bart.'s; N. B. Fadia, Bombay and Middlesex; T. Finey and T. Fritz, London; Ruth C. Galletly, Royal Fr H. Gordon, Durham; I. Gordon, St. Bart.'s; E. Hac Leipzig and London; F. F. Hellier, Cambridge and Lee S. K. Jatar, Bombay and London; D. T. Jones and W G. Jones, Guy's; S. Kin, King's Coll.; L. R. Lalw Bombay and London; Florence M. Lessing, Charing Cr A. L. Light, Leeds; E. R. R. Mellon, Guy's; E. C. Murr London; D. A. Nicoll, King's Coll.; J. R. O'Neill, Lee C. R. L'E. Orme, Cambridge and King's Coll.; E. R. Passe, Melbourne and London; P. H. L. Playfair, Cambri and King's Coll.; T. R. Plummer, Oxford and St. Georg H. D. Pyke, Bristol; T. G. Reah, Cambridge and Lond H. Richards, Guy's; V. C. Robinson, Cambridge and Bart.'s; S. A. Scorer and S. Shone, Guy's; H. Stark, Bart.'s; B. Stewart, Cambridge and Leeds; B. P. Calcutta; P. R. Thambugala, Calcutta and Middles Ercenwin A. Utting, St. Mary's; and Sybil O. Willia Royal Free.

Surgery.—Annie D. M. Adams, King's Coll.; A. G. Adr St. Mary's; H. H. Aitchison, Oxford and London; G. Allan, Univ. Coll.; S. W. K. Arundell, Middlesex; C. Bailey, Cambridge and St. George's; J. R. J. Beddard, Bart.'s; J. B. Blaikley, Guy's; R. M. Bolam, Cambri and Durham; B. J. Bouche, Guy's; J. J. Boulle, Lond A. M. Boyd, St. Bart.'s; G. H. Bradshaw, Cambridge St. Bart.'s; F. E. Camps, Guy's; C. E. Caudwell, W minster; M. A. Chamberlain, Manchester; F. Clif Cambridge and St. Thomas's; J. O. Clyde, Middlesex M. Cohen, Cape and Guy's; Elizabeth Cooper, Royal Fr Florence K. Costello, Charing Cross; J. F. Crabt Manchester; D. F. L. Croft, St. Bart.'s; H. W. D. Cr Guy's; S. H. Croot, Cambridge and Guy's; L. E. Dai St. Thomas's; T. M. Davie, Middlesex; C. C. Davis, U Coll.; C. J. M. Dawkins, Cambridge and Middlesex; D. L. Derry, St. Thomas's; P. C. C. de Silva, King's Co

R. Doyle, Liverpool; J. T. Dunkerley, St. Bart.'s; H. A. Eason, London; Dorothy E. Eglington, Royal Free; J. S. S. Fairley, Cambridge and Birmingham; W. R. Forrester Wood, Cambridge and St. Bart.'s; G. H. V. Froggatt, Sheffield; M. Gamboa, St. Bart.'s; Dorothea L. Gee, Royal Free; W. N. O. George, Univ. Coll.; R. Glanvill, Guy's; D. R. Griffith, St. Thomas's; C. C. Griffiths, Liverpool; Gwendoline E. Grove, St. Mary's; F. R. Gusterson, St. Thomas's; W. G. Harvey, St. Mary's; C. F. Howes, St. Thomas's; Esme I. Hyam, Univ. Coll.; P. G. S. Kennedy, London; R. W. Knowlton, Cambridge and Middlesex; L. W. A. Lankester, Cambridge and St. Thomas's; J. C. Lee, Cambridge and London; A. Levy, St. Thomas's; K. Lindberg, Middlesex; A. G. Lloyd, Durham; O. V. Lloyd-Davies, Middlesex; R. M. B. Lowis, St. Thomas's; T. K. S. Lyle, Cambridge and King's Coll.; R. G. Macbeth, Oxford and King's Coll.; A. L. McFarlane, King's Coll.; E. R. R. Mellon, Guy's; K. G. Milad, St. Mary's; W. B. Millar, Middlesex; V. L. Misso, King's Coll.; G. Morgan, St. Mary's; G. H. Morley, Middlesex; L. H. Mottet and T. Nallainathan, Univ. Coll.; G. Na Ranong, St. Thomas's; G. S. Nightingale, London; Edith G. Niven, Univ. Coll.; W. G. Oakley, Cambridge and St. Bart.'s; R. I. O'Farrell, Sheffield; E. Ogden, Univ. Coll.; A. J. Parer and Keren I. Parkes, King's Coll.; C. T. E. Parsons, St. Bart.'s; A. P. Petigura, Univ. Coll.; A. S. Philps and I. Preiskel, St. Bart.'s; S. R. C. Price, King's Coll.; F. S. C. Pritchard, Guy's; C. B. Prowse, Cambridge and St. Bart.'s; H. D. Pyke, Bristol; A. F. Quarmby, Birmingham; T. G. Reah, Cambridge and London; J. B. A. Reynolds, Cambridge and St. Bart.'s; R. A. C. Rice, St. Bart.'s; G. L. Robinson, Cambridge and London; Alice I. Roughton, Cambridge; E. L. Rubin, Liverpool; D. J. Sagor, Cape and London; C. J. Sanderson, St. Bart.'s; G. H. Sanderson, Cambridge and Univ. Coll.; R. V. Sanzgiri, Bombay and London; N. Schachnowitsch, Guy's; C. P. Scott, St. Thomas's; Mary Scouloudi, Univ. Coll.; J. E. Semple, Cambridge and St. Thomas's; W. H. H. Serasinghe, Middlesex; Mary E. Sharp, Univ. Coll.; S. Shone, Guy's; F. J. G. Slater, Cambridge and Durham; E. Somasekhar, Birmingham; A. Somerville, Sheffield; A. G. C. Taylor, St. Thomas's; J. M. Taylor, St. Bart.'s; L. Taylor, Sheffield; K. A. Thomas, Birmingham; Phyllis D. Towell, Royal Free; S. A. Underwood, St. Mary's; M. H. Wace, St. George's; R. G. L. Waller, Westminster; C. J. Waring, London; C. M. E. Warner, King's Coll.; J. Wasserzweig, London; Olive C. Watkin, Charing Cross; K. Watman, Middlesex; C. E. W. Wheaton, St. Thomas's; D. C. Williams, Cardiff; G. M. Willoughby, Middlesex; Winifred M. Wright, Royal Free; N. Yacoubian, Birmingham; and H. S. T. Young, Cambridge and St. Thomas's.

Midwifery.—Margaret Abernethy, Royal Free; D. A'Brook, Univ. Coll.; Annie D. M. Adams, King's Coll.; A. G. Adrain, St. Mary's; H. F. Apthorpe-Webb, Cambridge and St. Bart.'s; Lucy E. Arthur, Nancy M. Badeley, and Vera R. T. Baylis, Royal Free; R. C. Bennett, St. Bart.'s; W. L. M.Bigby and J. B. Blaikley, Guy's; A. D. D. Broughton, Cambridge and London; H. H. Brown, King's Coll.; M. K. Bryce, London; D. S. Chowdhary, Punjab; J. O. Clyde, Middlesex; G. C. Cochrane, London; S. C. S. Cooke, Middlesex; P. A. Cooper, Univ. Coll.; Florence K. Costello, Charing Cross; D. W. C. Cox, Guy's; T. V. Crichlow, King's Coll; D. F. L. Croft and J. R. Crumbie, St. Bart.'s; T. J. Davies, Cardiff; C. C. Davis, Univ. Coll.; A. C. Dawes, King's Coll.; J. Donovan, Leeds; R. Fiddian-Green, St. Mary's; C. H. Forsyth, London; R. H. Francis, Cambridge and St. Bart.'s; G. H. V. Froggatt, Sheffield; M. Frohlich, Brussels and Middlesex; R. L. Frost, Guy's; Ruth C. Galletly, Royal Free; B. C. Ghose, Durham; A. Gilpin, King's Coll.; R. Glanvill, Guy's; G. H. A. Graetz, Cambridge and St. Bart.'s; F. W. H. Grenier, London; D. R. Griffith, St. Thomas's; Bryneilen Griffiths and Rosentyl Griffiths, Cardiff; F. R. Gusterson, St. Thomas's; E. J. Hamp, London; Amy F. Hankins, Punjab and Royal Free; C. K. Haskard, Adelaide and London; Dorothy C. Hay, King's Coll.; J. Hopton, St Bart.'s; R. G. S. Howe, Univ. Coll.; Mary A. Hughes, Charing Cross; C. H. Johnson, Guy's; H. C. Johnson, Minnesota; W. H. P. Jonas, Oxford and St. Thomas's; Mary E. H. Jones, Cardiff; R. A. Jones, Cardiff; J. S. Kapadia, Univ. Coll.; Mary L. R. Kennard, St. Mary's; P. G. S. Kennedy, London; S. Kin, King's Coll.; R. W. Knowlton, Cambridge and Middlesex; M. Kokia, Westminster; L. W. A. Lankester, Cambridge and St. Thomas's; A. Levy, St. Thomas's; A. R. F. Lotaief, Durham; W. D. Lovelock-Jones, Cardiff; J. N. McArthur, Univ. Coll.; A. L. McFarlane, King's Coll.; Hilda M. C. Macmahon Garry, Liverpool; J. K. Marshall, Oxford and Guy's; S. N. Mathur, Lucknow; R. A. Maynard, Cambridge and St. Thomas's; W. B. Millar, Middlesex; G. Morgan, St. Mary's; G. H. Morley, Middlesex; L. H. Mottet, Univ. Coll.; E. C. Murphy and J. E. Myers, London; Q. St. L. Myles, Oxford and St. Thomas's; T. Nallainathan, Univ. Coll.; R. A. Nash, Guy's; T. H. Negus, St. Thomas's; P. L. Nirula, Punjab; E. Ogden, Univ. Coll.; J. R. O'Neill, Leeds; L. G. M. Page, St. Bart.'s; Keren I. Parkes, King's Coll.; A. P. Petigura, Univ. Coll.; I. Preiskel, St. Bart.'s; S. R. C. Price, King's Coll.; D. L. Pugh, Univ. Coll.; A. F. Quarmby, Birmingham; B. Rait-Smith, St. Bart.'s; Florence Ram, Cambridge and Sheffield; H. Richards, Guy's; R. D. Robinson, St. Bart.'s; Elizabeth B. Robson, Liverpool; T. S. Rodgers, Westminster; Irene H. Rogers, King's Coll.; B. Rothery, Cambridge and St. George's; H. W. Round, Birmingham; A. S. D. Russell, St. Thomas's; D. J. Sagor, London; H. K. Said, Charing Cross; G. H. Sanderson, Cambridge and Univ. Coll.; R. V. Sanzgiri, Bombay and London; J. E. Schneider, St. Thomas's; J. E. Semple, Cambridge and St. Thomas's; Mary C. Seward and Mary E. Sharp, Univ. Coll.; D. B. Smallshaw, Guy's; A. R. Smith, St. Thomas's; E. Somasekhar, Birmingham; A. Somerville, Sheffield; H. L. Spitz, Leipzig and Middlesex; V. Srinivasan, Madras; E. T. W. Starkie and Mary S. Stuart, St. Mary's; B. P. Sur, Calcutta; I. Taylor, King's Coll.; C. D. Trimble, Birmingham; S. A. Underwood, St. Mary's; Bertha D. Upton-Jones, Royal Free; M. H. Wace, St. George's; R. Warnecke, J. Wasserzweig, and S. N. Wasti, London; Olive C. Watkin, Charing Cross; L. H. Wharton, Bristol; C. E. W. Wheaton, St. Thomas's; J. S. Whiting, Cambridge and St. Bart.'s; A. W. Williams, Cambridge and Westminster; L. V. Williams, St. Bart.'s; G. M. Willoughby, Middlesex; W. R. Winterton, Cambridge and Middlesex; F. G. Wood-Smith, Cambridge and St. Bart.'s; M. G. Woolff, St. Thomas's; N. Yacoubian, Birmingham; and H. M. Yardley and H. S. T. Young, Cambridge and St. Thomas's.

Pathology (New Regulations).—Doris Ascough, Manchester; J. R. J. Beddard, St. Bart.'s; H. J. W. Bergh, St. George's; C. E. Caudwell, Westminster; S. C. S. Cooke, Middlesex; E. F. Hunt, St. George's; H. G. McGregor, Guy's; A. H. Nelson, Charing Cross; T. B. Pitts, Guy's; and J. E. C. Sayers, St. Thomas's.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The Old Students' annual dinner is to be held on Monday, Oct. 1st, with Sir D'Arcy Power presiding.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Honorary Fellowship of the College has been conferred on Dr. Hugh Hampton Young, clinical professor of urology in Johns Hopkins University, Baltimore.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The College will be closed for the summer vacation from Monday, August 13th, to Saturday, Sept. 15th, both days inclusive.

ST. MARY'S HOSPITAL ANNUAL DINNER.—The past and present students' annual dinner of St. Mary's Hospital will be held on Friday, Oct. 5th, at 7.30 P.M., at the Trocadero Restaurant, with Dr. E. G. Moon in the chair. The hon. secretary is Dr. A. Hope Gosse.

EXTENSION OF PAIGNTON HOSPITAL.—Sir Mortimer Singer has laid the foundation-stone of an extension of Paignton and District Hospital. The addition provides 20 more beds, a new private ward, a new out-patients' department, and an enlarged operating theatre.

BY a vote of 25 to 12 Bournemouth Borough Council decided on July 31st to sanction the use of unclaimed bodies at the Park Prewett Mental Hospital for anatomical examination at the University of Oxford. The request came from the Ministry of Health through the medical superintendent of the hospital.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL.—Princess Louise, Duchess of Argyll, recently laid the foundation-stone of a wing named after her. It will consist of five floors, the lowest being occupied by a large out-patient department. Each of the other floors will have a ward of 15 beds with operating theatre and the necessary adjuncts. The two upper floors will not be completed, in accordance with the policy of the institution, until the money is in hand. The total cost will be £52,000, of which £28,000 is now available. Princess Louise stated that there is a waiting-list of over 2000 cases needing operative treatment.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On August 13th begins a two weeks' course at the Infants Hospital, starting daily at 2 P.M. and consisting of lectures and demonstrations, together with special visits to other baby welfare centres. On August 27th the Queen Mary's Hospital will begin a two weeks' course in medicine, surgery, and the specialties. In the mornings there will be lectures and demonstrations, while in the afternoons there will be a choice of operations or medical, surgical, or special clinics, followed by a lecture after tea. Special courses in September have been provided as follows: Psychological medicine at Bethlem Royal Hospital; medicine, surgery, and specialties at Westminster Hospital; children at the Queen's Hospital; electrotherapy at the Royal Free Hospital; ophthalmology at the Royal Eye Hospital; orthopædics at the Royal National Orthopædic Hospital. In October the Fellowship will again arrange weekly clinical demonstrations in medicine, in surgery, and in ophthalmology, also a special series at the Wellcome Museum of Medical Science, and a series of lectures on gynæcology, children's diseases, and minor surgery. Detailed syllabuses and other information may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

A COURSE of study on Digestive Pathology will be held at the Hospital de la Santa Cruz at Barcelona from Oct. 5th to Dec. 10th under the direction of Prof. F. Gallart y Monés. Application for enrolment should be made to the Administración del Hospital de la Santa Cruz, Depositaría, Barcelona.

PRIVATE PATIENTS AT NORWICH.—Since the Private Patients' Department of the Norfolk and Norwich Hospital was opened in April last, 70 patients have been admitted, and recently not only has every bed been occupied, but there is already a small waiting-list. Payment of 30*s.* a year ensures treatment for a married man and his wife, with children under 16 whose income does not exceed £550 per annum; for a man and his wife, with no young children, whose income does not exceed £450, and for a single person with not more than £350 per annum.

CHRISTMAS MEDICAL TOUR ON THE CÔTE D'AZUR.—For the fifth year in succession a Voyage Médical International is being planned after Christmas to places of medical interest on the Mediterranean littoral. The rendezvous is Marseilles on Wednesday, Dec. 26th, to be followed by a day spent in visiting that port and another at Toulon. Then on successive days will be reached Hyères, St. Raphael, Cannes, Le Cannet, Grasse, Juan-les-Pins, Antibes, Nice, Menton, Monaco, Beaulieu, with opportunity for visiting the Roman citadel of La Turbie, the prehistoric grottoes of Grimaldi, the laboratory of Dr. Voronoff, the observatory of Nice, and other objects of scientific interest. Demonstrations and historical lectures will be given. For further information apply to the President of the Société Médicale du Littoral Méditerranéen, Dr. M. Faure, 24, rue Verdi, Nice, A.M., France.

THE LATE DR. C. H. NEWBY.—Dr. Charles Henry Newby, who died at his home in Ilfracombe on July 11th, was born at Ryde, Isle of Wight, in 1849, and was educated at the Merchant Taylors' School. After qualifying as M.R.C.S. in 1873 he held house appointments at St. Thomas's Hospital, and became surgical registrar there. As surgeon for the National Aid Society he was decorated with the Fourth Order of the Turkish Medjidie after the Turco-Serbian War of 1876. In 1880 he took the diploma of F.R.C.S. Eng. and in 1885 joined the expedition sent to Khartoum for the relief of General Gordon. For his part in this campaign he received the English war medal and the Khedival Star. In the following year he saw service in the Turco-Bulgarian War, gaining the Red Cross of Serbia and the Order of St. Save. Settling in practice at Southsea he became medical officer for out-patients at the Royal Portsmouth Hospital. On retirement to Ilfracombe in 1904 he associated himself with the work of the Tyrrell Cottage Hospital, and acted as its treasurer for many years. He leaves a widow and two daughters.

RATING OF LANCASHIRE HOSPITALS.—A conference to decide the basis of assessment for various buildings of a public character has been held at Manchester between the County Valuation Committee and the Rating Authorities and Assessment Committees of Lancashire. Seventeen assessment committees and 119 rating authorities were represented. It was decided that voluntary hospitals should be assessed, gross, at from 20*s.* to 30*s.* per bed, including the beds of the staff, with additions for facilities for outdoor and special treatment, and paying patients. Rate-maintained hospitals are to be assessed, gross, at from £2 to £4 per bed of patients and staff, likewise with additions for outdoor and special treatment. This scale is to be applied also to mental hospitals, sanatoriums, and similar institutions, with additions where they are justified on account of recreation and other purposes.

THE LATE DR. D. P. COOPER.—The death is reported from Surat, at the age of 93, of Dr. Dosabhoy Pestonji Cooper, a pioneer of Western medicine in the Bombay Presidency. Educated at the Grant Medical College, Bombay, where he graduated in 1863, he was two years later appointed medical officer to the Parekh Dispensary at Surat, where he settled in practice. He was first president of the Surat Medical Association founded in 1886 and in the following year was appointed Khan Bahadur for his public services. In 1899 he was awarded a certificate of merit for his work during the plague epidemic, and for a time he acted as civil surgeon for the city. For nearly 50 years, from 1867, he served the municipality as councillor and he was an honorary magistrate. Among other distinctions conferred upon Dr. Cooper was the Fellowship of the University of Bombay, and he was appointed honorary assistant surgeon to the Viceroy in 1885, receiving the Kaiser-i-Hind silver medal. He was a staunch and active Freemason for over half a century. Of his sons two are members of the medical profession.

KING GEORGE HOSPITAL.—In the recent speci distribution of the Wells legacies, King Edward's Hospi Fund for London set aside a grant of £10,000 towar the building fund of King George Hospital, subject conditions to be agreed. The Fund has been inform that steps will shortly be taken to invite the support of t charitable public for the establishment of the hospit The scheme, as submitted to the King's Fund, contemplat the provision of additional hospital accommodation the parts of Essex immediately to the East of Londo including the area for which such accommodation is pa ticularly needed owing to the development of post-w housing. The King's Fund proposes to summon a confe ence with a view to facilitating the execution of the schem

THE LATE DR. J. W. MELVILLE.—At the early a of 24 Dr. John Walter Melville died at Liverpool July 22nd after an operation for appendicitis. Educated the Barrow-in-Furness secondary school, and at the Unive sity of Liverpool, he qualified as a medical practitioner a as a dental surgeon in 1926, and graduated as M.B. in t following year. Last October he was appointed tutor dental surgery in the University of Leeds, but it w his intention to take up general surgical work, a he resigned this appointment in order to take up the po of resident house surgeon at the Royal Southern Hospit Liverpool, which he held at the time of his death. T funeral took place at Rampside, near Barrow, on July 25t

Medical Diary.

Information to be included in this column should reach in proper form on Tuesday, and cannot appear if it reach us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUAT MEDICAL ASSOCIATION, 1, Wimpole-street, London, W
Special two weeks Course in Infant's Diseases at the Infa Hospital, Vincent-square, Westminster.
MONDAY, August 13th.—2 to 3 P.M., Dr. W. E. Robinso Cases of Malnutrition and Intestinal Toxæmia. 3 3.45 P.M., Dr. Eric Pritchard: Lecture-Demonstratio Caloric Values. 4 to 5 P.M., Dr. Eric Pritchar Lecture, General Principles of Nutrition.
TUESDAY.—2 to 3.45 P.M., Dr. Eric Pritchard: Feedi Cases. 4 to 5 P.M., Dr. M. Maizels. Pathologi Demonstration. Cerebro-spinal Fluid.
WEDNESDAY.—2 to 3 P.M., Dr. W. E. Robinson: Cases Rickets and Scurvy. 3 to 3.45 P.M., Dr. Eric Pritchar Lecture-Demonstration. Modification of Cow's Mi 4 to 5 P.M., Dr. Elizabeth Karn: Lecture-Demonstr tion. Ultra-Violet Rays.
THURSDAY.—2 to 3.45 P.M., Dr. Eric Pritchard: Cases Tuberculosis. 4 to 5 P.M., Dr. W. E. Robinson: Lectu Respiratory Diseases in Infancy.
FRIDAY.—2 to 3 P.M., Dr. Eric Pritchard: Cases. 3 3.45 P.M., Dr. Eric Pritchard. Lecture-Demonstratio Diet of Children. 4 to 5 P.M., Mr. D. Levi: Lectu Pyloric Stenosis.
SATURDAY.—2 P.M., Visit to Home for Blind Babies, Chorl Wood; and to the Infants Hospital Convalesce Home, Burnham Beeches.
SUNDAY.—11 A.M., Visit to V.D. Centre, Thavies In Holborn-circus. Prophylactic Treatment of Syphilis Infants.

Appointments.

CAMPBELL, W. S. H., M.B., Ch.B. Edin., D.P.H., has be appointed Chief Medical Officer of Health to the Linds (Lincs.) County Council.
HOARE, E. F., M.D., Ch.B. Liverp., Coroner for East Susse in succession to the late Dr. W. A. Dow.
MACDONALD, A. D., M.B., Ch.B. Edin., Reader in Mate Medica and Therapeutics, University of Manchester.
SAUNDERS, J. C., M.B., B.Ch., D.P.H. N.U.I., Superintende Medical Officer of Health and Tuberculosis Officer Cork-le-Boro.
Certifying Surgeons under the Factory and Workshop Act BRAND, W. H. E., F.R.C.S. Edin. (Banchory, Kincardine and LEWIS, W. B. A., M.B., B.Ch. Camb. (Oswestry, Salop

Vacancies.

t London Hospital, Hammersmith-road, W.—Non-Res. Cas. O. £5 5*s.* per week.
chester, Royal Hampshire County Hospital.—Hon. Physician.

Births, Marriages, and Deaths.

BIRTHS.

S.—On July 27th, at St. Quentin, Broadstairs, the wife of Dr. J. W. W. Jepps, of a son.
ELL.—On July 22nd at Wellesley Hospital, Toronto, to Frances, wife of Dr. Eric A. Linell—a daughter.
YD.—On August 1st, at 29, Bramham-gardens, S.W., to Olive, wife of W. Ernest Lloyd, M.D., M.R.C.P.—a son.

MARRIAGES.

GETT—SIMPSON.—On July 30th at St. Martin-in-the-Fields, London, William Ingledew Daggett, M.A., M.B. Camb., F.R.C.S. Eng., to Eileen Hilda, youngest daughter of Colonel and Mrs. Simpson, of Fowey, Cornwall.
IS—IRVINE.—On July 31st, at All Saints' Church, Panarth, Kingsley Wassell Lewis, M.B., B.S., M.R.C.S., L.R.C.P., to Florence Henrietta, third daughter of the late Henry O. Irvine, of Southerndown, and of Mrs. Irvine, of Salisbury-avenue, Panarth.
NNES—MASTERMAN.—On August 1st, at St. Giles's Church, Camberwell, the Rev. Angus Campbell Macinnes, to Florence Isabella Joy Masterman M.B., B.S. Lond.
TIN—GARFIT.—On July 31st, at Partney Church, Lincolnshire, Peter Henry Martin, B.M., B.Ch., M.R.C.P., to Phyllis Mary Garfit, third daughter of the late Bartholomew Claypon Garfit and of Mrs. Garfit, of Dalby Hall, Spilsby.
RO—LOWTHER BOUCH.—On August 2nd, at Ackworth Parish Church, James Gibson Munro, M.B., Ch.B., of Kimberley, Nottingham, to Lilias Anne, eldest daughter of J. Lowther Bouch, Rector of Ackworth.
LEFIELD—DEAN.—On July 28th, at Caerphilly, South Wales, Bernard Graham Scholefield, D.M., F.R.C.S., to Queenie, younger daughter of Mr. and Mrs. C. H. Dean, of Berwyn, Caerphilly, South Wales.

DEATHS.

.—On August 5th, at Langdale, Salisbury-avenue, Harpenden, William Burt, M.B., B.S. Lond., late of Finchley.
OLL.—On August 1st, at 3, Artillery-mansions, Woolwich, Louis Ely Reginald Carroll, M.R.C.S., L.R.C.P.
SCH.—On August 1st, George Frederick Hentsch, L.R.C.P., M.R.C.S.
H.—On August 1st, at Mosley House, Boothstown, James Marsh, M.B., C.M., late Medical Officer of Health, Atherton.

.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE RED CROSS IN TIME OF PEACE.

AFTER ten years of peace it is well to be reminded that this generation can never lose the scars of war; the work of the Red Cross emphasises facts which most of us find it easy to forget. The eighth report of the joint council of the Hospital of St. John of Jerusalem and the British Red Cross Society, which covers only nine months, shows that their excellent work for ex-Service men has continued actively. During this period 308 tuberculous officers were helped, bringing the total since 1914 to 17,798. As time goes by, applicants find it increasingly difficult to satisfy the Ministry of Pensions that their disability is due to war service, and the Red Cross gives the necessary assistance while a case is pending. Other officers have finished their course at a sanatorium, but need financial aid in securing specialties of diet while on home treatment. Others, again, are helped with travelling expenses to Switzerland or the Riviera. The hospital at Brighton was filled the whole time, and some of the patients were very seriously ill when admitted.

An important activity of the fund is the provision of materials and training in various handicrafts for pensioners who cannot train in the hospital workshops. Approximately 1000 men were helped in this way during the nine months. The industries taught are increasingly popular and the medical superintendents speak highly of the great benefit conferred. Ex-Service men in Ministry of Pensions' hospitals are sent Christmas presents of the value of 5*s.* each, and over 2000 of them were cheered in this way on Christmas Day, 1927. About 13,000 men were taken out for drives or rides, or transported to entertainments. Although a number of Ministry hospitals have been closed, the diminution in the number of men still under treatment is not very great; they are simply being concentrated in larger institutions. The Emergency Help Committee, founded to give temporary emergency relief to ex-Service men and their widows and dependents, has also continued active. Many men, handicapped by disability, have been rendered self-supporting. 18,353 new cases were assisted during 1927, but no fewer than 12,187 applications were refused on the ground that there was no definite end in view or that they were ineligible or undeserving. One activity of this committee is to provide motor attachments to invalid chairs, and already 357 heavily disabled pensioners have thus been enabled to travel about without fatigue. The Games and Comforts Fund made 238 grants for wireless and cinema apparatus, musical instruments, cigarettes, clothing, bagatelle and billiard tables, gramophones, and all kinds of outdoor and indoor games. The Spero Firewood Factory for tuberculous ex-soldiers had to be closed down, but was fortunately able to reopen as the result of a special grant. From the medical point of view the factory proved most successful. The experiment of Scio House—a comfortable, "homely" institution for ex-officers suffering from advanced tuberculosis—has proved an unqualified success.

No less important than this continuing war work are the activities of the Red Cross Home Service Ambulance Committee, whose vehicles carry a steadily increasing number of sufferers every year. Modern methods of diagnosis and treatment depend so much on immovable mechanical apparatus that the mobility of the sick is becoming really important. In 1920, each of 273 ambulances carried an average of 125·6 patients. In 1927 the average had increased to 267·7. First-aid boxes are being set up on main roads, and all over the country members of the Order and Society spend their week-ends and holidays on the roads, armed with splints, bandages, and dressings. Considering the fact that 138,774 accidents, involving death or injury, took place on the roads of the United Kingdom in 1926, the Council feels justified in appealing for more voluntary workers for this service. The mobile X ray service is being increasingly used and a second car has been equipped.

THE INTERNATIONAL HANDBOOK OF CHILD CARE AND PROTECTION.[1]

SINCE the first edition of this remarkable book appeared in 1924 200 pages have been added to its bulk and 3*s.* to its price. The somewhat inadequate "International Who's Who" has disappeared, its place being taken by a useful bibliography, and a much fuller index than heretofore enables the inquirer to find more easily the particular information he desires. Mr. Edward Fuller, who has carried out

[1] Third edition. Compiled from official sources by Edward Fuller. London: Longmans, Green and Co., Ltd., and the Weardale Press. 1928. Pp. 646. 10*s.* 6*d.*

the arduous task of compiling a record dealing with 300 countries or political units, excuses himself for inequalities of presentation, pointing out that the details are supplied in various forms and a dozen languages, that some replies are received two years after sending out the questions—though the Governor of Guadeloupe is the only one bold enough to state that his statistics are authoritative for five years—while there is no sort of agreement among English-speaking people as to what they mean by "child welfare." Many surprises are met with in turning over the pages of this volume; for instance, that child welfare work has been carried on in Afghanistan since 1910, that both infant vaccination and education are compulsory in the Bahamas but neither in Barbados, that abortion is legal in Russia, that no less than 2,300,000 children in Germany are cared for by public and private charity, and that the infant mortality-rate in the Republic of Cuba is only 31 per 1000, falling to 20 in the city of Havana. Mr. Fuller says that his purpose is to place his readers "in possession of information which is not available in any other single volume or in any one country (and in many instances not at all outside official documents not always published) leaving each reader to marshal the facts as he will and to make his own comparisons." The book is admirably suited to fulfil this aim.

NITRITES IN SEA-SICKNESS.

Dr. J. F. Pearcy and Dr. D. B. Hayden, of Chicago,[1] believe that sea-sickness is mostly, if not entirely, due to over-stimulation of the vestibule. In studying the effects of blood pressure on labyrinthine function, they found that sodium nitrite, by lowering the blood pressure, markedly diminished nystagmus and past-pointing after rotation. When Dr. Hayden found himself among 16 sea-sick people on an Atlantic boat he naturally tried sodium nitrite. Eight of them were left to suffer and remained ill for an average of two days, despite injections of epinephrine hydrochloride. The eight who took grs. 3–5 of sodium nitrite every two hours were all comfortably eating on deck in an average of four hours, and did not relapse. Dr. A. Sellheim,[2] of Leningrad, has treated 20 cases with a drop of a 1 per cent. solution of nitroglycerine in water or two drops of a ½ per cent. solution on the tongue. All the patients recovered. There seems to be scope for the trial of these methods, but vigorous reduction of blood pressure is not without its dangers, and the nitrites and nitroglycerine are drugs to be handled with considerable caution. If their effect should prove to be mainly psychological some milder vehicle for faith would be preferable.

A HANDY CARD-INDEX CLIP.

Messrs. Cooper, Dennison, and Walkden, Ltd. (7 and 9, St. Bride-street, London, E.C. 4), have sent us specimens of the "transparent" card hinge, invented by Dr. J. M. F. Whitby, to which attention has already been called in our columns. The device consists of two circular discs of transparent linen stitched together down the centre and having their opposing surfaces gummed. They are adapted for use in any card-index cabinet, as one record card can be quickly attached to another which has been filled up, thus making up a book of cards. The salient points about the hinges which are already in use by insurance practitioners and others are their cheapness, ease of manipulation, saving of labour, and readiness to hand. The price is 1*s.* per box of 100, 7*s.* 6*d.* per box of 1000, postage extra.

ANIMALS AND REASON.[3]

Dr. Warden, who is assistant professor of psychology in the Animal Laboratory, Columbia University, has written a brief account of how man throughout the ages has interpreted what he has been able to learn of animal life. The story of science in its larger meaning, he points out, is the story of an unceasing attempt on the part of man to understand his own place in the natural order of things, and he surveys accordingly the facts that have emerged and the opinions that have been expressed along the lines of comparative psychology indicating the rise of this branch of learning to an exact science. Noting that the space made available by the format of the series has only permitted the briefest attempt at an historical survey, his hope is that he may be able to place modern movements in proper historical perspective, and his object is attained. He deals with his subject under five headings, ancient animal lore, the Greek influence, the psychology of the Early and Middle Ages (the period covering the decline of the Roman Empire and the rise of Christianity which terminates with the sixteenth century), the period between the opening of that century and the establishment of Darwinian principles, and, finally, with t experimental methods which have brought comparati psychology to-day into an exact science. He regards Darw as the founder of modern psychology, inasmuch as when t doctrine of evolution had been generally accepted, "a measu of sanity in interpreting animal behaviour" became apparen but in a technical closing section—the longest—he sho where experimental methods have conducted the leade of the science. A very interesting little book.

NEW PREPARATIONS

Citobaryum.—This preparation is manufactured by H. Napp, Ltd., 3 and 4, Clements Inn, Kingsway, London. Wi the large modern developments of X ray work, the diagnost meal has become a familiar technical process, while bariu sulphate is largely replacing bismuth carbonate as an aid f outlining the alimentary tract. The manufacturers ha put the preparation on the market, the insoluble sulpha for X ray diagnosis, in a palatable and convenient form, a it is supplied in packets of 150 g., this quantity being es mated as needed for one examination. Full directions f use are supplied and stress is laid upon the fact that t granular external character of the salt disappears if t directions are followed leaving a meal free from objectionab sedimentation.

Shadoform is a special preparation for the ready produ tion of a liquid barium meal issued by the British Dr Houses, Ltd., Graham-street, City-road, N. 1. Its advanta lie in the ease with which the meal can be prepared— requires merely to be mixed with water—in the t cream-like consistency of the meal and the compl absence of lumps or grit, in its palatability and opaci and in the remarkably long time the solid matter rema in suspension. Shadoform is issued in packages of fo sealed boxes, each of which contains the equivalent 4 oz. of chemically pure sulphate of barium.

SIR MORELL MACKENZIE'S BIRTHPLACE.

To the Editor of THE LANCET.

SIR,—Some of your readers interested in medical histo who happen to be in the neighbourhood of Leytonsto London, may like to glance at the house where Sir Mo Mackenzie was born in July, 1837. The old house, w the worn stone steps and the shop in front, is now emp and dilapidated, and if not shortly pulled down may painted by a new tenant out of knowledge. The ho stands at the corner of Browning-road, Leytonstone, wh is a small antiquated road turning off the main road, qu close to the "Green Man" Inn, which is advertised a stopping place by all the tramcars and buses. In all obituaries I have read no mention is made of the ex spot. The visitor will find a tablet let into the side of house about 20 ft. from the ground, which commemora the fact.

I am, Sir, yours faithfully,

London, August 7th, 1928. OBSERVER

ACTIVE TREATMENT AFTER ELECTRICAL TRAUMA.

ELECTRICAL injuries, perhaps more than any other, for conservative treatment as a general rule. The rea for this is the tendency of the affected tissues to necrosis hæmorrhage. Nevertheless, as Prof. S. Jellinek[1] has recen pointed out, active measures are called for by cert definite indications. Rupture of vessels may give trou in the third or fourth weeks, and however carefully ligatu are applied they are always liable to cut through the alte vascular wall. Cerebral œdema calls for lumbar puncti an operation which this authority recommends as a first- measure in all electrical accidents. Amputation and surg intervention, usually with the object of removing dama tissues, should be rigidly avoided except when there disturbance of the general health and its cause is undoubte the local lesion. Prof. Jellinek insists strenuously that ordinary rules of pathology frequently do not apply h and that hundreds of these operations are performed unne sarily. A fourth indication is the division of nerves by or metallic edges. Otherwise the more conservative treatment of electrical injury the better.

[1] Wien. klin. Woch., 1928, i., 766.

CLOSING OF WAR HOSPITALS.—Two of the gr Birmingham War Hospitals, Uffculme and Sovrento, closed last week, being no longer required for their orig purpose. From 1919 to 1923 Uffculme was devoted so to orthopædic and limb cases; since then it has been for general surgical and medical cases, and as a centre the supply and repair of artificial limbs. Sovrento, wh was used mainly for paraplegic cases, will now becon maternity home under the City Health Committee.

A Contribution
TO THE STUDY OF
CHOREA.
HE SYMPTOMS WHICH RESULT FROM INJURY OF THE CORPUS LUYSII.

BY J. PURDON MARTIN, M.D. BELF., M.R.C.P. LOND.,

TANT PHYSICIAN TO THE NATIONAL HOSPITAL FOR NERVOUS DISEASES, QUEEN-SQUARE; AND PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH.

HE corpus Luysii, corpus subthalamicum or body uys, is an almond-shaped ganglion situated just w the optic thalamus (see Fig. 1); it lies immedi- internal to the fibres of the pyramidal tract as pass down from the internal capsule to the pes he cerebral peduncle. Medial to it is the red eus and that complicated space known as Forel's ; below it is the substantia nigra. Its greatest h measures about 1·2 cm. The fibres which r it come almost entirely from the lenticular eus, passing in considerable numbers across and nd the internal capsule; of its efferent fibres , as will be shown, descend into the mid-brain nd the substantia nigra, and a few cross under floor of the third ventricle to the corpus Luysii ie other side. The knowledge of its connexions ill very incomplete. Of its functions I think it r to say that there has hitherto been no knowledge, ough a few observers have drawn tentative lusions from isolated cases.

a paper read at the combined meeting of the rican Neurological Association and the Neuro- al Section of the Royal Society of Medicine, held ondon last July, a description was given of the wing case, in which the only lesion found post em to which the symptoms observed during life d be ascribed was a small hæmorrhage destroying practically limited to the body of Luys of the ide of the brain.

History of the Case.

he patient was admitted to the Seaman's Hospital r my care on Feb. 12th, 1927, and subsequently ferred to the National Hospital, Queen-square. was a man of large build, aged 62, formerly a an, and latterly employed as a night watchman oard ships in dock. He had had no previous ses, but at the time he came under observation very atheromatous arteries, his systolic blood ure was 190 mm. Hg, and he had a considerably ged heart; the Wassermann reaction in his blood positive.

cept for frequent headaches during the preceding months, he had been well until Feb. 8th. On that ing, about 8 o'clock, just after arriving home his night's work, he felt giddy, staggered, and a severe pain in the right side of his body. He own for a little, then felt better, had a meal and to bed as usual. When he woke up at 4 o'clock e afternoon he tried to take a cup of tea sitting bed, but his right hand "shook" so violently he spilled most of the tea and he could not bring up to his mouth. Even when his wife held the he could not drink normally, but, as his wife ibed it, "he slopped the tea into his mouth gulped it down." When he got up that evening to his ship his right arm was twitching and ging about widely, and "he was throwing his leg about," but, with some assistance from his he managed to walk. When his wife saw him , two hours later, the involuntary movements had become much worse, but in the morning he managed to walk home. His condition remained much the same for the next 36 hours, but on the evening of Feb. 10th he became very agitated and unreasonable, turned on his wife as he had never done before, and in such a way that she was afraid of his violence; his involuntary movements were then worse than ever. The next day he remained in the same angry and uncontrollable mood, and in the evening made his way down to the ship. On the fourth morning after the onset of his illness he fell in his house, and that day he was brought to hospital.

Condition on Admission.

When I first saw him, and until his death 15 days later, his condition was as follows. While he was awake his right arm and leg were unceasingly tossed about in a violent chorea. The movements occurred at all the joints of these limbs, but an unusually severe involvement of the shoulder and hip and elbow and knee gave them an amplitude not often seen in chorea. In form they presented every combination of flexion, extension, and rotation; they were quite irregular. They were free, quick movements, unhampered by any degree of spasticity. Their violence was such that the skin had been knocked off the knuckles and other parts of the affected hand, and also of the inner sides of both knees. The movements were continuous during the waking state, though they varied somewhat in intensity, being less when the patient was alone, and worse when he was called up to answer questions or perform test movements. With a great effort the patient could hold the right arm steady for about 20 seconds, every muscle of the limb being then taut in contraction. The right side of the head and face and the tongue were involved in the chorea, and to some degree the right side of the trunk. The patient usually lay with his head and eyes turned to the right, and he seemed to try to put the right hand under his head in order with his head to fasten it down on the bed and so restrain its movements. The movements of the face were less than was to be expected from the severity of the chorea in the limbs. In the early days of the illness articulation, though affected, was still distinct, but later it became greatly slurred. Swallowing was performed by spasmodic gulps. Breathing was always irregular, and was sometimes difficult owing to the irregular movements of the muscles of the throat, chest, and abdomen. All these abnormal movements ceased entirely during sleep. The patient's facial expression suggested great anxiety and restrained anger, and this seemed to be a true reflection of his mental state; during his stay in hospital he was at times irrational and uncontrollable, especially towards night; in the latter part he was at times disorientated, and often in a frenzy. Associated with the movements was a moderate degree of sweating, almost confined to the affected side; the patient while awake always looked hot, and the jactitated limbs felt warm and moist. The body temperature, as registered on the chart, remained steadily at 97° F. until a few hours before death. The temperatures of the two sides of the body were unfortunately not compared.

Neurological Examination.

Further neurological examination revealed few other abnormalities. Voluntary power was normal in all the limbs. There was no sensory loss to pin-prick or light touch; at the first examination, but not subsequently, there seemed to be a slight hyperæsthesia of the choreic arm. The sense of position was normal, and pointing tests, including the Bránáy tests, were accurately performed; pointing with the right hand was accompanied by choreic deviations of the moving limb, and the point indicated was touched by a finger, as it were, in flight. The appreciation of vibration was normal. The tendon-jerks were present in both arms and about equal on the two sides, those in the right arm being, if anything, less; the knee-jerk was definitely less on the affected (right) side than on the left; the ankle-jerks were approximately equal. The plantar

responses were both definitely flexor throughout the illness. The abdominal reflexes were not obtained. The optic discs were normal, the pupils were approximately equal, but neither was quite regular; both reacted to light, and as far as could be determined they reacted also to accommodation; the external ocular movements were full, but the eyes when at rest were usually deviated to the right. Except for the abnormal movements in the face, throat, and tongue, the functions of the remaining cranial nerves were normal.

The patient died on the twentieth day from the onset of the chorea. A post-mortem examination was performed by Dr. J. G. Greenfield 12 hours after death, and the brain was hardened for a week in 10 per cent. formol saline before being cut. Subsequent section showed a recent hæmorrhage destroying the body of Luys of the left side—i.e., of the opposite side of the body to the chorea; except for scattered hæmorrhagic points there was no other lesion in the brain.

The examination of serial microscopic sections showed that in its vertical extent and anteroposteriorly the injury corresponded closely with the limits of Luys's body, and in lateral extent it transgressed these limits only by one or two millimetres in each direction. A small dorsal fragment of the corpus Luysii remained. The red nucleus was not reached by the hæmorrhage at any level, and none of the known important fibre-tracts was interrupted.

The photograph which is shown here (Fig. 2) is that of a horizontal section of the brain, which passes on the left side through the lesion below its middle, and through the upper half of the red nucleus; the right half of the brain is cut appreciably lower (as is shown by the section of the optic tract), and only a small portion of the body of Luys of that side is seen. The actual area of destruction is seen surrounded by a zone of staining. Its length at this level was almost exactly 1 cm., and its breadth ½ cm., but at a higher level its breadth was slightly greater. A more detailed description of the pathological anatomy is given in the original paper.[1]

FIG. 1.

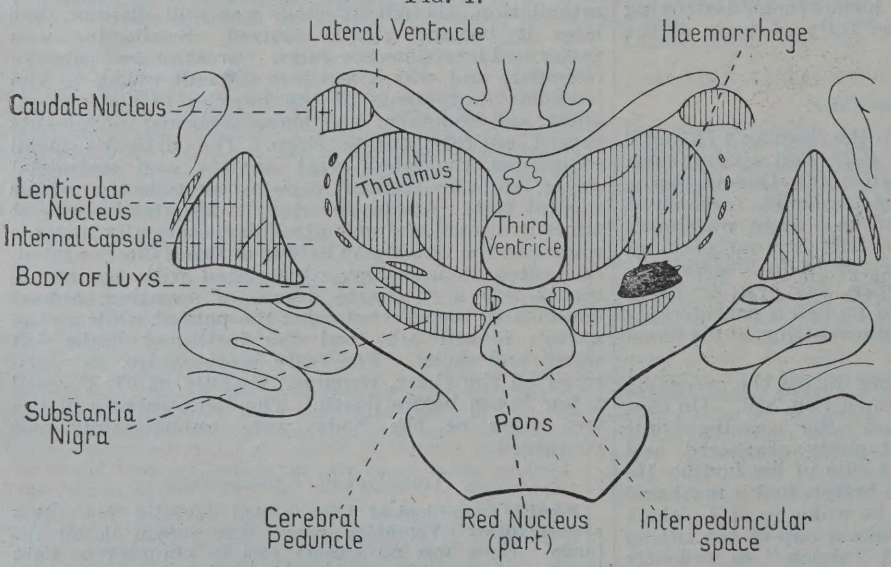

Diagram of a vertical transverse section of the brain to show the anatomical relations of the body of Luys and the extent of the hæmorrhage in the case described.

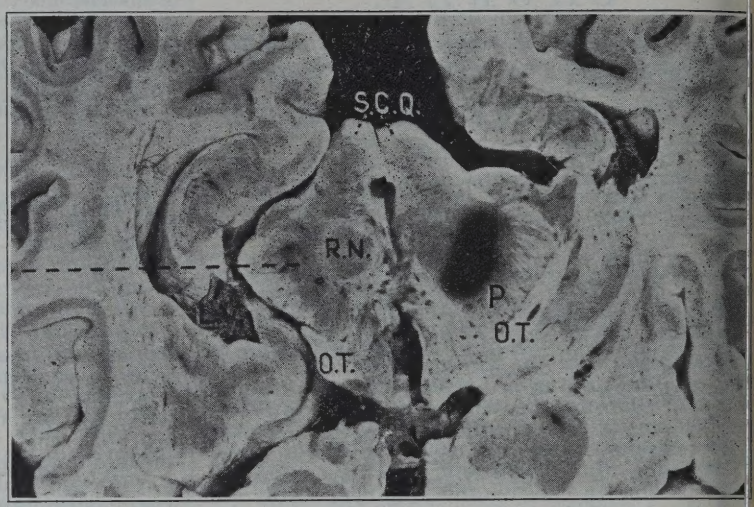
Similar Cases in the Literature.

It is impossible to assess the physiological significance of the findings in such a case except in conjunction with similar findings and with experimental work. There are in the literature of the last 50 years 12 cases, sufficiently described, in which localised lesions of the body of Luys have been found after death, and a number of other cases in which the body of Luys was involved in more extensive lesions. Closely comparable to the case described above are those of Fischer, Campora, Pette, Canfield and Putnam, Economo and Jakob, of which I give the following brief notes:—

FIG. 2.



Horizontal section of the brain passing through the lower half of the hæmorrha... The area of actual destruction is surrounded by a zone of staining. B.L. = b... of Luys; R.N. = red nucleus; S.C.Q. = superior corpora quadrigemina; P. = cerel... peduncle; O.T. = optic tract; and L.V. = left ventricle.

Fischer, 1911.—Fem... aged 72. Sudden onset ... left hemichorea with v... large movements; f... considerably affected. Arti... lation and swallowing ... turbed. No ment... disturbance. Death on ... fourth day.

At post-mortem exami... tion a hæmorrhage ... found destroying the ri... body of Luys "and c... this." There was a su... ficial cortical defect on ... orbital surfaces of b... frontal lobes.

Pette, 1922.—Female, aged 69. Carcinoma of the br... three years before. Sudden onset of chorea of the whol... the left side. Death four weeks later.

Post-mortem examination showed a carcinomat... deposit the size of a pea in the right regio-subthalamica;

y of Luys was mostly destroyed (private communication); nucleus, thalamus, corpus striatum, and cerebellar ıncles all intact.

anfield and Putnam, 1884.—Male, aged 59. Slight right ichorea for several weeks, then sudden exacerbation. ɜ little involved. Articulation affected. No sensory Knee-jerk and ankle-jerk normal on right, absent on The patient could walk without assistance. Death e weeks after the onset of severe chorea.

ɔst-mortem examination showed a hæmorrhagic softening size of a large pea " in the medial half of the left crus, ɔsite the posterior portion of the thalamus; it involved substantia nigra and the pes beneath to a depth of 6 mm., and the tegmentum above almost to the nucleus r. The only ganglionic matter involved besides the tantia nigra was the so-called ganglion of Luys."

Economo, 1910.—Male, aged 71. Sudden onset of ent chorea of the left side 24 hours after a slight stroke ing some weakness of this side. Articulation affected. nsient right hemi-amblyopia. Mental disturbance. th seven days after the onset of the chorea.

ɔst-mortem examination revealed a hæmorrhage the size cherry-stone lateral to the red nucleus, in the substantia a and in the tegmentum, involving the regio subthalamica the corpus Luysii, and extending ventrally into the pes.

ıkob, 1923.—Female, aged 75. Sudden onset of left ichorea with large movements. Conjugate deviation he eyes sometimes to right, sometimes to the left. lition remained unchanged for three weeks; then 24 ɔs before death the patient became comatose and the s of the left side were at rest and very flaccid. On the ɔ side some spasticity. Death from broncho-pneumonia ıov. 3rd, 1921.

ɔ post-mortem examination a recent hæmorrhage was , entirely destroying the body of Luys on the right side, strictly confined to this ganglion, pushing Forel's iles H 1 and H 2 upwards; it was sharply demarcated the internal capsule and the substantia nigra. Medially, tended beyond the bounds of Luys's body, but did not h the red nucleus. Many hæmorrhagic points in the l ganglia of both sides. Some small hæmorrhagic foci ıe left internal capsule.

ith these I think we may group the following , though its anatomical description is not quite ıise.

agnan,[2] 1870.—Male, aged 73. Sudden onset of right ichorea. Violent movements. Death after five days. ɔst mortem " a section made through the left cerebral ıncle at its insertion into the optic thalamus revealed a ɔrrhagic focus of the size of a small nut." This was the recent cerebral lesion.

ɔnfirmatory evidence of the results of injury to corpus Luysii is afforded by the remaining cases, hich there was more than one small lesion in the n, one of the foci in each case destroying Luys's y.

ich cases have been recorded by Greiff, Touché, Bianchi nd case), Bremme and Matzdorff.[3] In all of these the ical syndrome was the same as in the cases already ibed, with some complication corresponding to the r lesions. In Bremme's case the damage was caused secondary carcinomata, in Bianchi's by patches of losis, and in the other cases by hæmorrhage or throm- ɔ. Matzdorff's report requires special mention; it was rently in the press at the time at which the paper I have red to was read, and the author, citing seven of the s I have mentioned, described independently as " The rome of the corpus Luysii " the main elements of the ɔtom-complex put forward under a similar title in my r. But Matzdorff relates that his patient had been seen ıg life by Prof. Jakob, and the latter, who had had a ar case several years before, expressed the opinion arscheinlichkeitsdiagnose) that there was a lesion of the us Luysii of the opposite side of the body to the chorea. must surely be the first case in which such a diagnosis been correctly made, even tentatively, during life, and arks a stage in the knowledge of the subject. Patho- gally Matzdorff's case is important because the softening entirely confined within the limits of Luys's body.

f less physiological value than the foregoing, but worthy of mention, are cases in which the corpus sii was involved in a lesion which extended widely nd its borders. Such are Bianchi's first case erculoma), and the cases of hæmorrhage recorded ewandowsky and Stadelman, and by Lloyd and kelman; probably the case recently described by [4] falls also into this group. In all of these cases ame choreic syndrome was present during life.

To the experimenter the body of Luys is not easily accessible, and the only experiments actually involving it are those of d'Abundo.[5] He found that in kittens his lesions of the subthalamic region (including Luys's body) invariably produced a chorea of the opposite side of the body, and rotation of the head to the side of the chorea.

Fibres Descending from the Corpus Luysii.

It has been said that the efferent connexions of the corpus Luysii are very imperfectly known. In my case, blocks of cerebral tissue from above and below the site of injury were impregnated by the Marchi method, and these when cut showed a small but definite bundle of degenerated fibres beginning immediately caudal to the destroyed corpus and passing down the mid-brain (see Fig. 3). It lay immediately behind the substantia nigra, and soon

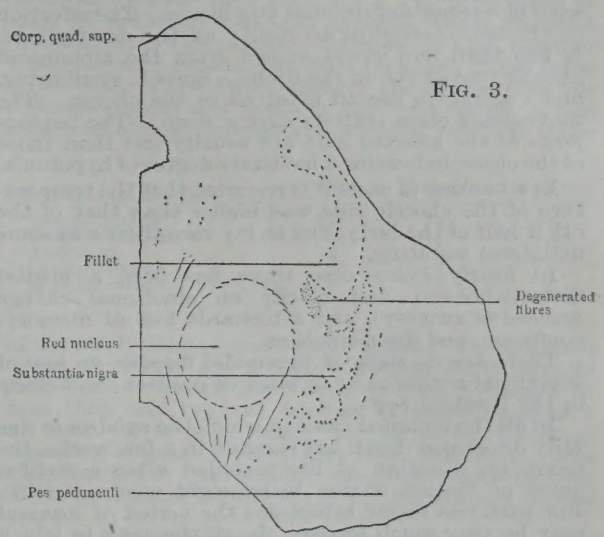

FIG. 3.

Outline drawing of a section through the upper part of the left half of the mid-brain to show the position of the degenerated fibres.

joined the medial margin of the medial fillet. It seems most probable that the fibres composing this bundle issue actually from the corpus Luysii, and it is consequently to be expected that a small lesion interrupting them would give rise to the same symptoms as an injury to the body of Luys itself. However that may be, there are in the literature of the last 50 years only two cases in which hemichorea was attributable to a focal lesion at a lower level than the corpus Luysii, and in both these cases the sites of damage, though widely divergent, were so situated that this bundle of fibres was interrupted. The first is a case by Bianchi in which the only damage in the left half of the brain (to account for a right hemichorea) was a patch of sclerosis which lay mainly in the middle third of the pes pedunculi and had spread backwards through the substantia nigra to involve the medial portion of the fillet. The second is a well-known case described by Bonhoeffer in which the main lesion was due to a carcinomatous mass at the decussation of the superior cerebellar peduncles, but to the left of this there was a small deposit interrupting the medial margin of the left fillet; the patient had had a right hemichorea. With the knowledge of the other cases now at our disposal it seems legitimate to ascribe the symptoms in this case to the latter lesion.

In animal experiments chorea of the opposite side of the body has been produced by Economo and Karplus[6] by lesions which interrupted, inter alia, the medial margin of the fillet, and by Lafora[7] by lesions directed towards the superior cerebellar peduncle, and therefore also interrupting these fibres. Chorea, as far as I have discovered, has not been obtained experimentally by any lesions other than those mentioned.

It is therefore in conformity with the clinical and experimental facts that interruption of the fibres which appear to descend from Luys's body gives rise to symptoms similar to those resulting from injury to the body itself. Unfortunately it has not been possible to follow the degenerated fibres to their termination, and their ending is unknown.

The Syndrome of Destruction of the Corpus Luysii or of its Descending Fibres.

A study of the foregoing cases in more detail than it is possible to give them here enables us provisionally to attribute a group of symptoms to the destruction of the corpus Luysii or interruption of its descending fibres, with the consequent release or disturbance of the function of other structures. The chief symptom is a violent chorea of the opposite side of the body, with unusual involvement of the shoulder and hip, and, therefore, with movements of unusual amplitude. The affection of the face, according to nearly all the descriptions, is less than one would expect from the amount of choreic movement in the limbs. Speech, swallowing, and respiration are all involved in the chorea. The movements cease entirely during sleep. The tendon-jerks of the affected side are usually less than those of the other, indicating a moderate degree of hypotonia.

In a number of cases it is recorded that the temperature of the choreic side was higher than that of the other half of the body, and in my case there was some unilateral sweating.

In nearly every case there has been a mental disturbance—at first chiefly an emotional change (excessive anxiety), and afterwards loss of memory, confusion, and disorientation.

There are no signs of pyramidal disease, no loss of superficial sensation or of sense of position, no defects in the pointing tests.

In all the recorded cases in which the syndrome was fully developed death has resulted in a few weeks, the naximum duration of life recorded after a sudden onset of violent chorea being eight weeks (Greiff). But with less severe symptoms the period of survival may be very much longer. In all the cases in which the mode of death can be ascertained, except Bonhoeffer's case in which death was due to erysipelas, the patients died of broncho-pneumonia. Touche's patient, who lived for a year after the onset of the chorea, had three attacks of broncho-pneumonia during that time. It is remarkable that none of the patients died of cerebral hæmorrhage or of cardiac failure. I think that the tendency to broncho-pneumonia is possibly to be correlated with the respiratory disturbances of the chorea and to be included as part of the fully expressed syndrome.

Remarks on the Pathogenesis of Chorea.

Since chorea commonly occurs in association with widespread inflammatory or degenerative changes in the brain, it has perhaps not been generally realised that it might result from a focal lesion. In this paper no reference is made to the inflammatory or degenerative choreas, but we must ask ourselves in what way focal lesions in the situations we have described can result in chorea. It is now generally conceded that chorea is a "release phenomenon," i.e. that it arises from the excessive or irregular activity of intact structures from which a controlling or guiding influence has been withdrawn. The cases that have been related do not indicate in what structures the impulses arise which originate the choreic movements, nor what structures must be intact in order that chorea may occur. Two factors indicate, however, that the impulses arise at a lower level than the body of Luys and that the controlling influence over them is normally exerted by the body of Luys itself. In the first place, we are dealing with a descending anatomical system of fibres; fibres arise in the lenticular nucleus and pass to the body of Luys, and another set of fibres arising in the body of Luys continues the path downwards to the mid-brain. Such a system must, by reason of its anatomical arrangement, exert its action downwards; in other words, the control which the destruction Luys's body apparently interrupts is a downwa directed control, and so the impulses over whic is normally exerted must be arising at a lower le Secondly, there is no valid evidence that fo injuries above the body of Luys result in cho Numerous animal experiments have been perform of which those of Kinnier Wilson [8] on the lentic nucleus and the recent series by Delmas-Marsalet [9] the caudate may be mentioned, and in no insta has chorea or any symptom comparable to cho resulted from a lesion of these structures. Of clin cases of pure chorea resulting from focal lesi nearly all the recorded instances have already b mentioned. It is true that there remain four—th of Vogt,[10] Conos,[11] Austregesilo and Gallotti,[12] Fragnito and Scarpini [13]—and that in all of these chorea has been attributed to a lesion in the caud or putamen. But it can be said without fear contradiction that as a basis of argument the three of these are valueless. The fourth is a m more important record, but is open to cer objections, and the authors, who express themse with great reserve on its merits, state definitely t they are unwilling to give any general applica to their findings. Consequently we must for present be guided by the experimental evidence assume that focal lesions of the caudate or lentic nucleus do not give rise to chorea. If chorea c not occur unless the lesion is as low in the sys as the corpus Luysii, and does occur when t structure is damaged, the control which norm prevents chorea must be exerted by the co Luysii itself. As long as that primary contro intact, chorea from a focal lesion does not seem occur.

Physiological Action of the Corpus Luysii.

Of the physiological action of the corpus Lu little can yet be said, except that it exerts a co over impulses arising in certain lower struct which are probably situated in the mid-brain. T is no unanimity as to the nature of the impu which cause chorea, and until we know their na we cannot deduce the normal function of the co Luysii from the symptoms liberated by its dest tion. The anatomical connexions of the co Luysii with the lenticular nucleus suggest that t is a higher control of its activities represente certain cells widespread in the striatum and pallid and it may be that by these nuclei the functio Luys's body is normally directed in relation other cerebral functions.

A NOTTINGHAMSHIRE ORTHOPÆDIC HOSPITA

The Duke of Portland has given a large site at Harlow W near Mansfield, for the erection of an orthopædic hos Owing to legal difficulties a public Guarantee Compan been formed for its erection. Last year, in Nottin alone, there were more than 100 cripples for whom treat was not available.

A CLINICAL STUDY OF THE HUMAN AND BOVINE TYPES OF TUBERCULOSIS IN MAN.

JOHN T. MORRISON, M.B. EDIN., F.R.C.S. ENG.,
SURGEON, ROYAL SOUTHERN HOSPITAL, AND CONSULTING
RGEON, CITY SANATORIA FOR TUBERCULOSIS, LIVERPOOL.

THE investigations out of which this paper developed e originally undertaken by Prof. J. M. Beattie, he University of Liverpool, to determine whether incidence of human and bovine tuberculosis was same in Liverpool as in other parts of the country. bacteriological work has all been carried out him from clinical material supplied from the Sanatoria, the Royal Liverpool Children's spital, the Liverpool Stanley Hospital, and private ctice. It is therefore fairly representative of all es of non-pulmonary tuberculosis and of various s and social strata. The correlation of the clinical ditions with the bacteriological findings brought many points of interest which are important so far as they contribute to a more accurate wledge of the disease. My conclusions should egarded as indications rather than demonstrations he truth. So far as they go, I think they are ified by ascertained facts, but larger numbers needed before generalisations can be made. necessity a certain amount of selection has crept The material is from consecutive cases, but e, as a rule, it is the more hopeful cases that reach operating-theatre the mortality results are of absolute value. On the other hand, a certain unt of comparison between different groups is missible.

ne hundred cases were investigated bacteriologi- y during the years 1923–24–25. One or two e been excluded as certainly not tuberculous. e patients cannot be traced, and so final con- ions cannot be drawn about them, although vious notes render them useful for certain istics.

Inoculation Failures.

considerable number of cases inoculated, ough clinically undoubted cases of tuberculosis, e no result in the test animals. Of these gative" results one should be eliminated, as the ent had a severe streptococcal infection and the nals died of streptococcal septicæmia. This es 31 cases, almost one-third, for inquiry. The erial used in these 31 cases was: in 66 per cent. caseous debris of softening glands or actual pus; 25 per cent. caseating bone foci; and peritoneal l and tuberculous granulation tissue in 4 per cent. a. As the proportions are practically identical he series of cases proved definitely bovine, it ns that the source of the material and its physical perties have no important bearing on its failure produce disease in animals. In other words, ough pus was used in a considerable percentage ases—and tuberculous pus is notoriously deficient tubercle bacilli—the negative results cannot be ibuted to this factor, as pus was used in just as y cases which gave positive results. So far as it s, this is an argument against the criticism that city of organisms in the material used was onsible for the absence of tuberculosis in the ratory animals.

may be said that such organisms as were ent were enfeebled by exposure to powerfully agonistic bodies in the serum of patients ly immunised against tuberculosis. If this so, the high state of immunity is not reflected the clinical progress of the patients. In those er consideration the recovery-rate (or proportion apparent cures) was only 73 per cent. None of 18 cases of undoubted bovine tuberculosis traced two years or over showed any signs of active ase—i.e., the recovery-rate was 100 per cent. I do not think that the effects of general immunity in the patient are of any great importance here. On the other hand, local conditions seem to have a bearing upon the results. It is conceivable that fibrosis, for instance, is inimical to the organisms in lesions in one part of the body, while in other parts the disease might even be progressive. The average duration of the lesion in the cases giving "no result" was 4·3 years (though several cases had apparently relatively short histories), while the "human" cases had lasted 2·3 years and the "bovines" only just over one year. That the results were not merely fortuitous is shown by the fact that repetition of the inoculations confirmed the original negative finding in several instances.

In case it should be pleaded that these patients were not tuberculous at all, those in whom any clinical doubt arose have been excluded. The proportion of cases of actinomycosis and syphilis which simulate tuberculosis is very small. No case giving a positive Wassermann reaction has been included. The table shows that, in the distribution of the disease over the different organs and systems, the "no result" cases represent almost exactly the average between those

—	Bovine.	Human.	No result.
Lymph glands	25	11	20
Bones and joints	5	13	7
Abdomen	2	0	2
Genito-urinary	1	1	0
Miscellaneous	1	1	1

of definitely human and bovine origin. The negative cases, therefore, are probably derived fairly equally from both types of infections, so that it cannot be said that one type of bacillus is more frequently at fault, or is more easily influenced by the local curative actions of the body, than the other. For this reason the "no result" cases have been ignored in the statistical inquiries into the human and bovine cases.

Regional Distribution.

The bovine bacillus is found to account for 75 per cent. of the cases of tuberculous glands in the neck. That is rather less than has been found in certain other districts, where the percentage has been placed as high as 90 per cent.[1] Inquiry into the age incidence may account for this apparent variation. Bovine infections were present in only about 28 per cent. of the bone cases. The figures relating to abdominal and genito-urinary cases—mainly because they are relatively seldom submitted to operation—are so small as to be valueless. In the main the figures are comparable to those for the country generally.

A study of the age factor throughout the whole series shows that 65 per cent. of the human infections were over 12 at the age of apparent onset, while 35 per cent. were 20 or over when symptoms first appeared. Among the bovine cases, on the other hand, only 15 per cent. were over 12 when attention was drawn to the disease. Of these 15 per cent., although the infection was bovine, three out of the five were not only over 12 but actually between 20 and 25 when evidence of tuberculosis was first obtained. While, roughly, 75 per cent. of all bone tuberculosis is due to the human bacillus, in patients over 15 the figure rises to 82 per cent., and in those under 15 about 70 per cent. is human in origin. This figure is one of great significance.

Of the cases of lymphatic gland infection in children 16 per cent. yielded the human type of organism and 84 per cent. the bovine. This more closely approximates to the 90 per cent. quoted above from the published results of work done entirely amongst children. Nevertheless, the fact remains that in Liverpool 16 per cent. of cases of glandular tuberculosis are due to human bacilli—i.e., infection from active cases of phthisis. In contrast to this 62 per cent.

[1] A. P. Mitchell: Infection of Children with Bovine Tubercle Bacillus, Brit. Med. Jour., 1914, i., 125.

of glandular disease in adults is due to the human tubercle bacillus. In fact, in adults about 72 per cent. of all surgical tuberculosis is the result of infection with the human organism. That implies that a very large proportion of cases of adult non-pulmonary tuberculosis have also a pulmonary focus—active or latent. This should increase the gravity of the prognosis in these cases, should make prolonged after-care imperative, and should be a warning against the indiscriminate use of general anæsthetics, which may aggravate pulmonary disease. An X ray of the chest should always be taken before operation on any adult with surgical tuberculosis.

Family History.

It was thought that a study of the family history would in many instances give a clue to the type of disease present—i.e., that a history of phthisis in a member of the older generation would be found in infections with the human bacillus, and that in bovine infections the older generation would be healthy, and other members of the same generation diseased. Here, however, great difficulties are encountered. There is a very widespread feeling that it is disgraceful to have a case of tuberculosis in the family. Unfortunately, the sense of disgrace does not lead to the general adoption of a more hygienic way of life, the use of non-tuberculous milk, and stricter measures to prevent the spread of infection, but only to concealing the shameful fact or to heaping up mounds of sand in which to bury the head, so that at least the horrid thing is out of sight. Infection of collateral members of the family is surprisingly seldom reported in bovine infections, though, of course, striking instances do occur. This is another indication that the soil is at least as important as the seed in the development of tuberculosis. In human cases, on the contrary, a bad or decidedly suspicious history of pulmonary disease was found in 31 per cent. Over and over again one can elicit nothing more than "grandmother always had a cough and mother died of pneumonia."

Apart from a study of the family history, attempts at determining the portal of entry were singularly unsuccessful. It was definitely recorded that, among the bovine cases, two apparently originated in glands draining the area in which an open wound had existed a short time before. In bovine cases the milk naturally falls under special suspicion. In four cases, one of which was in a well-to-do intelligent family, it was stated that the milk had always been boiled. This, of course, proves nothing, for such matters are often left to maids, who may be untrustworthy. Moreover, other articles of diet, such as butter and cream, may be carriers of the bacillus. The tonsils were diseased and the teeth carious in many patients with cervical glandular disease, but in several others they were not obviously at fault. Little weight, unfortunately, can be attached to this observation as, apart from the possibility of tuberculous infection passing through a tonsil without leaving indisputable evidence behind, it has been definitely shown that naked-eye examination is no criterion as to the presence or absence of actual tuberculous disease in a tonsil.[1]

Results of Treatment.

The results of treatment are strikingly different in the different groups. For instance, as already stated, all the 18 bovine cases traced were found in good health, and their lesions quiescent, while no less than 18·75 per cent. of the human cases were dead within three years; 68·75 per cent. were cured or apparently cured. I do not think this necessarily means that the bovine infections are harmless, while the human are deadly. Apart from the long period of illness, the expense of treatment, and the permanent crippling often caused by bovine infections, many patients die in the early years of life from meningeal, pulmonary, and abdominal tuberculosis, and are never seen by the surgeon.[2] The course of the two infections is apparently very different. Those to the bovine organism begin, as a rule, early in l though not necessarily in the very earliest ye and may lead to a comparatively acute and viru process. Should this not prove fatal, the mani tations of the disease become more and more chr until after early adult life it practically disappe Many believe that the human infection is contra early—i.e., within the first four years of life—that thereafter, if not rapidly fatal, it lies lat perhaps for many years. Be that as it may, "surgical cases" the disease is one that tends attack those of maturer years (65 per cent. o 12 at the time of apparent onset) and, unlike bovine type, it never disappears, and all ages liable to suffer. It may become very chronic, the immunity established evidently falls far sh of that produced by the bovine organism, as is sh by the very considerable mortality in the hur variety.

[1] Dr. Louis Cobbett's evidence, Report of Royal Commission on Tuberculosis, 1907.

SOURCES OF INFECTION IN NON-PULMONARY TUBERCULOSIS.

By C. O. STALLYBRASS, M.D. Lond., D.P.H. Liverp.,
ASSISTANT MEDICAL OFFICER OF HEALTH FOR THE CITY OF LIVERPOOL.

For the past seven years I have noted, from reports of our sanitary inspectors on cases of n pulmonary tuberculosis, whether there was a hist of exposure of the patient to a pulmonary occurring in the patient's family. In all these pati there is a considerable presumption that the infec was of human origin. The total number of c so examined is now 4469, and these are presente Table I., separated according to the anatomical site the usual classification. The numbers are sufficie large to have some statistical validity.

TABLE I.

City of Liverpool.—Cases of non-pulmonary tuberculos 1921–27, divided into Group A—those with *no* histor exposure, and Group B—those with a history of exposur open cases of tuberculosis occurring within the family of patient.

Site of disease.	A.—No exposure.	B.—Exposure.	Proportion of total expressed per cent.		Difference of percentage.*	Pr a err dif e (1 ce
			A.	B.		
Bones and joints ..	974	89	24·3	19·3	−5·0	±
Abdominal	859	116	21·4	25·1	+3·7	±
Peripheral glands ..	1277	156	31·9	33·8	+1·9	±
Meninges and brain	418	61	10·4	13·2	+2·8	±
Skin..	124	15	3·1	3·2	+0·1	±
Urinogenital ..	92	3	2·3	0·7	−1·6	±
Other, or ill-defined	264	21	6·5	4·6	−1·9	±
Total	4008	461	99·9	99·9	—	

* This column gives the excess (or defect) of the percenta cases occurring in Group B over the percentage of cases occu in Group A.

The significance of these figures lies in the last columns, which give (1) the excess or deficienc the percentage of cases having a history of exposu infection in comparison with the percentage of c having no such history, and (2) the probable erro this difference in percentage. The usual criterio the significance of a difference of two rates is tha should be three or more times its probable e With this proviso the following deductions may made from the table. In Liverpool—

1. Tuberculosis of the bones and joints is significa more frequent in those having no history of exposur a human source of infection.

2. Tuberculosis of meninges and abdominal tubercu are significantly more frequent in those having a his of exposure.

3. Tuberculosis of peripheral glands is significantly in cess in those known to be exposed to human infection, but e significance is not so high as in 1 and 2.
4. The other groups either lack precision or are not merous enough to be significant.

The deductions from these figures indicate that berculosis of bones and joints is more often of vine origin than meningeal, abdominal, or, with less rtainty, peripheral glandular tuberculosis. This ference is somewhat contrary to the usual opinions hich are based largely on the work of Eastwood and riffith, and of Park and Krumwiede. Griffith has ven figures of cases bacteriologically investigated; ey indicate that 46·5 per cent. of cervical glandular ses, 41·3 per cent. of abdominal cases, and 18·3 per nt. of bone and joint cases occurring in children ere caused by bovine bacilli.

I give now a table (II.) of non-pulmonary cases of berculosis, slightly modified from figures given by r. A. S. Griffith at the National Milk Conference in ondon in 1922. I have computed the probable rors of the percentage.

TABLE II.*

—	Cases.	Bovine and per cent.	Probable error.
rvical glands	116	54 (46·5)	±3·12
ne and joint	476	87 (18·3)	±1·20
pus	126	64 (50·8)	±3·00
nito-urinary	17	3 (17·6)	±6·23
st-mortem material ..	159	39 (24·5)	±2·30
ningitis	12	2 (16·6)	±7·25
Total	906	249 (25·8)	±0·95

* These figures, unfortunately, do not give the abdominal ses.

Owing to their numerical insufficiency the figures of cteriological examination of material from cases of n-pulmonary tuberculosis are not beyond statistical iticism, despite the immense labour involved in taining them. Mr. E. D. Rudolf[1] performed this sk some years ago, and his results are given in able III.

TABLE III.

Age-period in years.	Total cases.	Bovine infections and per cent.	Maximum variation possible.
-5	47	14 (29·79)	18·87
-10	108	31 (28·71)	12·31
-16	62	7 (11·29)	11·37
-25	15	3 (20·0)	29·2
er 25	29	0 (0·0)	0·0
Total	261	55	—

It appears from these figures that the number of ses occurring in persons over 16 years of age is sufficient for comparison, and the figures in this spect are not a fair sample of the population. In

TABLE IV.

Cases of non-pulmonary tuberculosis among persons on cords of tuberculosis dispensaries in Liverpool, 1921–27.

Classification.	Adults and per cent.	Children and per cent.	Total.	Children. Per cent. of total at site.

dominal ..	83 (10·91)	471 (25·27)	554	85·0
ripheral glands	314 (41·26)	764 (40·99)	1078	70·9
her	87 (11·43)	160 (8·58)	247	64·8
Total	761 (100·00)	1864 (100·00)	2625	71·1

der, then, to make a useful comparison it is cessary to confine attention to children. The gures given in Table IV., from information provided by Dr. B. T. J. Glover, show the distribution into adults (over 15 years) and children, of 2625 cases on the records of the tuberculosis dispensaries in 1927, and are probably a fair sample of the whole.

The incidence upon adults and children is not markedly different except in the case of abdominal tuberculosis, which is predominantly a disease of children, and to a lesser degree in respect of bone and joint tuberculosis which has a somewhat disproportionate incidence upon adults. I therefore returned to my records and abstracted the cases with a history of exposure, dividing them into adults and children. The result is shown in Table V.

TABLE V.

Cases with a history of contact with a pulmonary case.

Classification.	Adults and per cent.	Children and per cent.	Total.	Ratio of children to adults (per cent.).
Bones and joints	24 (22·64)	65 (18·31)	89	2·7
Abdominal ..	10 (9·48)	106 (29·86)	116	10·6
Peripheral glands	51 (48·11)	105 (29·58)	156	2·0
Other	21 (19·81)	79 (22·25)	97	2·8
Total	106 (99·99)	355 (100·00)	458	3·31

It would take too long to find the proportion of children in all the cases of non-pulmonary tuberculosis, and so I take the records of the tuberculosis institutes, in which the children amount to 2625 out of 4469, or more than half the total, and, with this proportion as a basis, eliminate from the total given in Table I. the proportion which may be regarded as probably adults (Table VI.).

TABLE VI.

Estimated cases of non-pulmonary tuberculosis *in children* in the City of Liverpool during 1921–27, divided into (A) those with *no* history of exposure, and (B) those with a history of exposure to a pulmonary case of tuberculosis.

Site of disease.	A.—No exposure.	B.—Exposure.	Proportion of total expressed per cent. A.	Proportion of total expressed per cent. B.	Difference of percentage.*	Probable error of difference (per cent.).
Bones and joints ..	772	65	24·18 ±1·01	18·31 ±1·38	−5·87	±1·71
Abdominal	829	106	25·97 ±1·05	29·86 ±1·64	+3·89	±1·95
Peripheral glands ..	945	105	29·60 ±1·09	29·58 ±1·63	−0·02	±1·96
Other, or ill-defined	646	79	20·24 ±0·96	22·25 ±1·49	+1·01	±1·77
Total	3192	355	99·99	100·00	—	—

The deductions from Table I. have to be somewhat modified for children:—

1. Bone and joint tuberculosis is significantly in excess in those having *no* history of exposure to human infection.
2. Abdominal tuberculosis is in slight excess in those having a history of exposure.
3. Peripheral glandular tuberculosis occurs with as high a frequency among those exposed as among those not known to be exposed to human infection.

There is therefore a direct contradiction between the figures I now publish and the results of bacteriological investigation. Possibly the discrepancy arises from differences in the age-distributions of the populations investigated; or there may be geographical differences; or the cases bacteriologically investigated may be representative of only a portion of the whole—e.g., the more severe cases.

It is of some interest to note that, although the collection of the data has occupied seven years, their analysis has taken only two days; yet it is this comparatively slight labour which is usually shirked. Use has been made of Pearson's tables for the value

[1] THE LANCET, 1922, i., 1146.

of χ, Miner's tables of $\sqrt{pq}$, Barlow's tables of squares, and a calculating machine for the multiplication and division.

I have to express my thanks to Dr. A. A. Mussen, Medical Officer of Health for the City of Liverpool, for permission to publish these figures.

THE PERMANENCE OF THE SCHICK NEGATIVE STATE.

BY H. J. PARISH, M.D., M.R.C.P. EDIN.,
AND
C. C. OKELL, *M.C.*, M.B., M.R.C.P. LOND.

(*From the Wellcome Physiological Research Laboratories, Beckenham.*)

IT is customary to assume that the state of immunity to diphtheria which is indicated by a negative Schick test is permanent. This is suggested by much experimental work on the duration of active immunity, but, because modern methods of diphtheria prevention are of such recent date, it is impossible to examine the expectation by actual experience in human beings. This paper records the results of retesting children at intervals after a negative Schick test was obtained, the maximum interval being seven years. An investigation has also been made of the capacity of response to artificial immunisation of any who may have become positive after having once been negative. 973 children were retested one to seven years after the first negative Schick test. All were negative with the exception of 28 (2·9 per cent.). 541 children were retested after one to three years, 191 after three to five years, and 241 after five to seven years. After one to three years the percentage of positives was 2·6, after three to five years 5·3, and after five to seven years 1·7, differences which are probably not significant.

The 973 children may be subdivided into two groups—viz., 533, who were negative to the original Schick test one to seven years previously, and 440, who were positive on the original Schick test and became negative only after injections of prophylactic mixtures (vide table). 527 children (98·9 per cent.) of the 533 who were negative on the original Schick test one to seven years previously were read as negative on retest, and 6 (1·1 per cent.) as positive. 418 (95 per cent.) of the 440 in the immunised group were negative on retest and 22 (5 per cent.) were positive. It will be seen that there is little difference in the Schick-positive rate of the two groups. Further tests may, however, confirm the observation that children who have been immunised by artificial methods show a somewhat higher percentage of positives on retest than those who have become immune in response to the weaker stimuli which they may receive naturally. It may be possible that some individuals can be immunised only by the larger stimuli introduced in prophylactic mixtures, and that these people are prone to lose some of the antitoxin they may thus with difficulty acquire. One or two individuals who gave faint reactions may have been wrongly read as positive in our recent retesting, but it is better to read as positive one or two doubtful reactors who are really immune than to pass as Schick-negative a susceptible subject. The Schick level of immunity corresponds to about 1/100th to 1/30th of a unit of antitoxin per c.cm. of blood. The Schick-negative reactor contains more than this amount and the Schick-positive reactor less.

Group 1.—533 Children Negative on Original Test.

In six children who were originally Schick-negative one to seven years previously a positive Schick result was obtained, indicating a quantity of antitoxin less than 1/50th of a unit per c.cm., but four of the six became negative within a brief interval of the Schick test injection. Thus, two weeks after the Schick test was made, a blood sam from one child was examined and found to contain half unit per c.cm. Blood samples from two other childr contained 1/10th unit of antitoxin per c.cm. within o week of the Schick injection, and a fourth child had 1/100 unit in two weeks and gave a Schick-negative reaction three weeks. Only 2 (0·4 per cent.) of the children (ital in table) required an injection of an immunising mixtu One had no detectable antitoxin in seven days, was given immunising injection of toxoid-antitoxin at 14 days, h 1/100th unit at 21 days, and was definitely negative a fortnig later. The other gave a positive reaction to a second re-Schi one week after the first, had less than 1/1000th unit antitoxin, and was given 1·0 c.cm. of an immunising mixt after two weeks and had 1/250th unit of antitoxin in fo weeks. This child has recently had another 1·0 c.cm. d of a prophylactic mixture and is still under observation.

The first four cases afford a parallel to the experiments Glenny and Allen (1922) on rabbits and guinea-pigs; th found that even 1/20th of a Schick test dose might act a "secondary stimulus" (Glenny and Sudmersen, 192 causing a rapid production of antitoxin in an animal wh had once been actively immune but which had subsequen lost some or all of its circulating antitoxin. The pres investigations have amply confirmed Glenny's observatio and there is no room for doubt that such a small amou of toxin as 1/50th of the guinea-pig minimal lethal dose l a pronounced influence on the amount of circulating antito actively produced, even of such a large animal as a hum being. This point has already been discussed by O'Br (1926), who instanced six cases in which a Schick test d produced a demonstrable rise in antitoxin in activ immune subjects. Similar observations have been made Kellogg and Stevens (1927).

Group 2.—440 Children Positive on Original Test and Negative immediately after Immunisation.

Twenty-two children (5 per cent.) in this group w positive on retest one to seven years later, but, as in first series, all but 2 (0·4 per cent.) developed antito rapidly in response to the stimuli of Schick injections. will be seen from the table that five of the children were s positive or partially positive on a second re-Schick in second or third weeks, but one week later all five l 1/25th to 1/5th unit of antitoxin. Two reactors who w more refractory (italics in table) were a brother and sis at a poor-law institution who had been very difficult immunise in 1925. They had both required two courses diphtheria prophylactic mixture—six injections of 1·0 c.c in all—but were, we think, undoubtedly Schick-negat finally, the boy within two months and the girl within f months of the last immunising injection. We are confid that the toxin dilutions with which these tests were m were of satisfactory potency on both occasions. On ret three years later both children were positive, and a one week and four weeks had no detectable antitoxin in blood (i.e., less than 1/2000th unit per c.cm.). Schick te in the first and fourth weeks were also positive. In the f week they were given 1 c.cm. of toxoid-antitoxin mixt Two weeks later the boy had 1/25th unit of antito indicating a fairly brisk response, but his sister still remai refractory and is receiving further injections.

Discussion.

It will be seen that there is very little differe between the two groups, which can now be conside together for purposes of discussion. At first sight percentage of children who had reverted to Schick-positive state after having once been negat is disquieting; 28 children (2·9 per cent.) of 973 w had been read as negative one to seven years previou were regarded as positive on retest. It is, howev reassuring that only four children (0·4 per ce required immunising injections, and that three of four showed a marked rise in antitoxin within one three weeks of a single dose of prophylactic mixtu It is doubtful, therefore, if the immunising mechan of these children would really have been slugg vis-à-vis an average infecting dose of virul organisms. The fourth child (0·1 per cent. of entire series) is in a different category, for she fai to show the slightest response to an injection 1·0 c.cm. of toxoid-antitoxin mixture.

The efficiency of the Schick dose of toxin a "secondary stimulus" is remarkable. It is a v small amount of toxin, originally founded on 1/5 of the guinea-pig minimum lethal dose, and combining power is equivalent to 1/1000th of a u

f antitoxin. If, however, a Schick-negative reactor as lost some of his antitoxin and becomes Schick-ositive, with little or no detectable antitoxin, the chick dose of toxin may be sufficient to make him ace again Schick-negative. In other words, active mmunity with the capacity for responding to a fresh imulus has remained, although circulating antitoxin ay have been lost. The fact that a Schick dose of oxin may be capable of stimulating the production of rculating antitoxin in an actively immune subject ust be borne in mind in connexion with every type experiment, in animals as well as in human beings, which serial Schick tests are used for the study of anges in immunity.

Over and above the series under review we have tested a group of 194 children who were negative on ie original test three months previously. All were gative on retest.

The observations, so far as they go, while not mpletely establishing the dictum "once Schick-gative, always Schick-negative," support the ore general statement "once immune, always mmune," if by immunity we imply a more ready otective response to the invasion of the specific oxin. One would expect such a "potential" mmunity to be sufficient to protect an individual gainst any serious infection by the diphtheria acillus.

* = Half a unit of antitoxin per c.cm. of patient's blood.
(*a*) Further details incomplete.
M = Toxoid antitoxin mixture −1·0 c.cm.
+, ±, −, = Reaction to Schick test.

Summary.

(1) 533 children who were Schick-negative on the iginal test were retested one to seven years later, id showed a 1·1 per cent. Schick-positive rate.

(2) 440 children who were Schick-positive on the iginal test were rendered Schick-negative by imunisation. When retested one to seven years ter 5 per cent. were found to be positive.

(3) In both these groups nearly all the "relapsed" hick-positive individuals rapidly produced circu-ting antitoxin in response to very small amounts of phtheria toxin, and could be considered as in a state active immunity.

We have to thank Mr. A. T. Glenny for valuable lp and advice as well as for the numerous blood rations which he has kindly done for us.

THE SCREENED RADON SEED IN THE TREATMENT OF MALIGNANT DISEASE.

BY PHILIP GOSSE, M.D. DURH.,
DEPUTY MEDICAL SUPERINTENDENT OF THE RADIUM INSTITUTE, LONDON;
AND
F. E. CHESTER-WILLIAMS, M.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER OF THE INSTITUTE.

FOR many years attempts have been made to treat tumours by implanting into them small pieces of capillary glass tubing containing radium emanation, but the results of such treatment have been unsatisfactory owing to the necrosis induced by this method, the glass capsule allowing the very destructive β rays to pass into the surrounding tissues.

The use of a capillary seed enclosed in a metal case having attached to it a fine thread has only recently been adopted in this country, though the method has been extensively used in America, particularly by Dr. Joseph Muir, of New York. No statistics of value can yet be given from a series of patients treated with seeds at the Radium Institute, London, but the results which are being obtained are encouraging, more especially in those cases which past experience has shown respond poorly to other forms of radium therapy. The object of this paper is to indicate the type of case most likely to derive benefit from this particular method of radiation and to give a brief description of the apparatus employed at this Institute.

Apparatus.—The seeds are cylindrical shells of platinum tapered at both ends, encasing a piece of capillary glass tubing containing radium emanation. Each seed is 6 mm. long and 1·1 mm. in diameter, having a wall of 0·3 mm. of platinum. Attached to the seed is a fine black thread which serves the dual purpose of marking the position of the seed in the tumour and facilitating its removal when the required dose has been given.

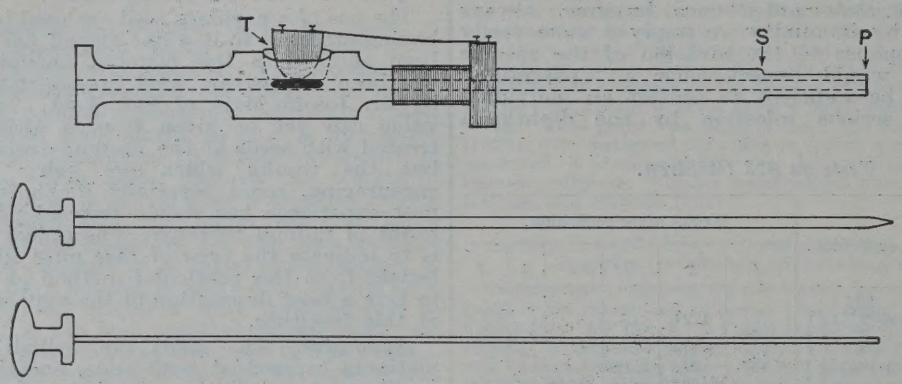
Dosage.—The majority of the patients have been treated with seeds each containing 1·5 millicuries of radon at the time of implanting, giving 200 millicurie hours of radiation if left in the tumour 14 days, by which time its radio-activity is negligible. The platinum screen 0·3 mm. in thickness allows about 90 per cent. of the gamma rays to pass through with less than 5 per cent. of beta rays.

Technique.—A trocar, with a special cannula as shown in the diagram, is used for implanting the seeds. The instrument having been loaded with a seed through the slot T it is inserted into the tumour up to the shoulder S. On withdrawal of the trocar the seed is forced into the lumen of the cannula by the spring and may then be pushed into the tissues with the stilette. It is a point of importance that the use of "introducers" with known but varying lengths from point P to shoulder S, enables the operator to plant seeds at known depths from the surface. As a general rule the seeds in a tumour should be about 2 cm. apart. Seeds may be implanted into tumours of the bladder through an operating cystoscope, using flexible introducers, and special instruments have been devised for use through the œsophagoscope and the proctoscope.

After-treatment.—The threads of seeds introduced anywhere in the buccal cavity may be bunched together, brought out through the mouth, and fixed to the skin of the cheek with adhesive plaster. Experience has shown, however, that patients tolerate the presence of the threads better if they are cut short ($\frac{1}{2}$ inch) and left free. While it is customary to remove the seed by gentle traction on the attached thread when its period of activity is over, no ill-effects have been noted in cases where the seeds have been left permanently in the tissues.

Advantages of the Method.

The advantages of seeds over other forms of radium applicators are: 1. By suitable spacing of the seeds throughout the whole tumour a uniform radiation is obtained. 2. The seeds are easily introduced and can be accurately placed in position. 3. Owing to their small size they are retained at the required site. This is of particular advantage in regions where the soft tissues are scanty—e.g., the alveolar margin. 4. Screened seeds without threads may be used in the treatment of tumours from which the recovery of radium needles would be difficult. 5. Patients are not confined to bed throughout treatment, but are able to attend as out-patients for regular examination. 6. Some hours after the insertion of radium needles into tumours of the tongue, for example, it is a common experience to find the heads of the needles becoming exposed, however completely they may have been buried at the time of operation. This is probably due in part to the movement of the tongue and in part to the traction of the heavy silk threads attached. Burns of the mucous membrane of the buccal cavity are likely to result unless special shields covering the alveolar margins and cheeks are employed. Seeds by remaining completely embedded in the tissues minimise the risk of burns and make the use of the cumbersome screens unnecessary. 7. Trauma is minimised, the seed causing little damage to the tissues both at the time of insertion and removal, owing to its size and shape. This is an important factor when dealing with malignant disease.



Cannula, trocar, and stilette, used for implanting radon seeds.

Types of Cases most Suitable for Seed Treatment.

While most malignant tumours may be treated as satisfactorily with seeds as with other forms of apparatus, their use at the Radium Institute has been confined to tumours which, owing to their position, would not receive uniform radiation by other methods.

These may be divided into two main groups. In the first are placed tumours where the retention of radium needles is difficult owing to the constant and unavoidable movement of the structures or to the small amount of soft tissue present. Examples of such tumours are those of the palate, the floor of the mouth, gums, frænum of the tongue, mucous membrane lining the cheek, tonsil, larynx, and pyriform fossa. Into regions such as these it was customary to insert comparatively large doses of radium to act for a short time. This method gave non-uniform radiation, sometimes followed by severe reaction and sloughing. Seed treatment of such patients gives them the triple advantage of a minimum of discomfort, uniform radiation, and a comparatively small dose of radium acting over a period of many days.

Into the second group may be placed tumours whose inaccessibility makes both the inserting and recovering of radium needles a difficult and frequently hazardous undertaking. It is unnecessary to give a list of these tumours which would include such commonly occurring ones as carcinoma of the œsophagus, stomach, prostate, rectum, and bladder. By employing suitable introducers radon seeds may be implanted into most of these, thus ensuring their complete radiation.

Mention must also be made of the suitability seeds for the treatment of small malignant nodul The small size of the seed enables it to be complete embedded at the site required. Needles inserted in such nodules frequently cause damage to the su rounding tissues which receive rays from the pr jecting ends, while small surface applicators a unlikely to remain in the required position for pr longed periods.

While this paper has been devoted to the descri tion of treatment with seeds alone, we have frequent found them of use in conjunction with other forms radium apparatus.

Illustrative Cases.

The following cases, in which the diagnosis h been confirmed by section, illustrate the resul which are being obtained after treatment of t primary lesion with radon seeds.

CASE 1.—*Surface epithelioma*, with little surroundi healthy tissue. Male, aged 61, Treated June 19 1928. Fu gating ep thelioma the right e 3·0 cm. diamete growing f two yea Four see were insert into t tumour a left there six day Preser conditio tumour longer pr sent, ulc healed.

CASE *Carcinom floor of mou* —Male, ag 59. Treated in May, 1928. Patient had a malignant ulcer the floor of the mouth, which had been noticed for abo three months. The ulcer, which had hard edges, extend from the mid-line, backwards beneath the tongue on t left side for about 4 cm. Ten seeds were inserted a allowed to remain for seven days. Present conditio ulcer is completely healed. Movements of the tongue a free.

CASE 3. *Carcinoma of alveolar margin.*—Male, aged Treated January, 1928. Patient had been unable to w his lower denture during the latter part of 1927. He w found to have a hard, coarsely papillated carcinoma on t alveolar margin of the right lower jaw. Four seeds w inserted for 14 days. On examination in March act disease was noted at each end of the area treated on first attendance. Four seeds were again inserted. Pres condition: a smooth white scar, soundly healed.

CASE 4. *Carcinoma; frenum of the tongue.*—Male, aged Treated March, 1928. This patient had a large carcinom tous ulcer in the mid-line beneath the anterior part of t tongue, spreading on to the floor of the mouth and on the alveolar ridge. Nine seeds were inserted for ten da Present condition: soundly healed, no sign of disease.

CASE 5. *Epithelioma of mucous membrane lining the cheek* Male, aged 70. Treated April, 1928. Patient had a s plaque with a velvet-like surface on the buccal muco membrane of the right side of the mouth. The disea area was 3·0 by 2·0 cm. in size with little surround infiltration. Six seeds were inserted for ten days. Pres condition: no evidence of disease.

CASE 6. *Epithelioma of mucous membrane of cheek a gum.*—Male, aged 84. Treated January, 1928. On exa nation this patient was found to have a malignant ulcer w indurated edges and base, involving the right alveo ridge and spreading on to the mucous membrane of the ri cheek. Five seeds were implanted and removed 14 d later. Present condition: no sign of disease in the mou

CASE 7. *Sarcoma of tonsil.*—Female, aged 73. Treat February, 1928. This patient had a firm, smooth swell in the left tonsillar region, which had been noticed three months. Six seeds were implanted. Three w recovered 14 days later and three remain permanently in tissues. Present condition: tumour has entirely appeared. Mucous membrane is intact.

ASE 8. *Carcinoma of palate.*—Male, aged 60. Treated e, 1928. This patient was found to have an ulcer ered with slough, involving the whole of the soft palate, extending forwards on to the hard palate. Ten seeds e inserted for 14 days. Present condition: after a very k reaction the ulcer is now almost healed.

ASE 9. *Carcinoma of pyriform fossa.*—Male, aged 52. ated April, 1928. This patient, who had experienced e dysphagia for six months, was found to have a large gating growth of the pyriform fossa, obscuring the cords. e radon seeds were inserted for five days. He was mined again at the end of June. His symptoms had been ved and the growth had shrunk to about one-third of original size, the left cord, and part of the right, being ble. Five seeds were again inserted and left for 14 days. first dose of radon was a small one owing to the possi- y of acute œdema and obstruction.

ASE 10. *Carcinoma of bladder.*—Male, aged 54. Treated ch, 1928. The patient complained of hæmaturia which ted in January, 1928. On examination he was found ave a large infiltrating growth on the right side of the e of the bladder. Eleven seeds were inserted into the our. Present condition: satisfactory; patient has no her symptoms, and all bleeding has ceased.

ASE 11. *Epithelioma of anal canal.*—Male, aged 54. ated December, 1927. This patient had a hard, craggy, rated growth encircling the anal canal immediately in the anal sphincter. Pain and the passage of blood rectum were prominent symptoms. Twelve seeds were rted through the skin and left in the tissues at the phery of the growth. On examination three months r no tumour could be detected. The pain and hæmor- ge had ceased.

eeds have been successfully planted into growths the œsophagus, but sufficient time has not yet osed to enable an opinion of the value of the hod to be given.

General Conclusions.

. The initial response of the tumour is more rapid n that seen with other forms of radium therapy. The local reaction is brisk in some instances. nother series of patients is now being treated with re heavily screened seeds.) (3) Owing to the very all size of the seed in proportion to the dose of ium it contains, there is a tendency on the part he surgeon to implant the seeds too close together, l this over-radiation may possibly account for the ere reaction occasionally met with. (4) The use seeds enables those tumours, which owing to their ure or position are difficult to treat by other thods, to receive thorough radiation.

We wish to express our gratitude to Mr. W. Lester on, physicist at the Radium Institute, and to his istant, Mr. A. E. Southon, for their helpful advice l skill in the preparation of the apparatus.

THE BROMSULPHALEIN TEST OF LIVER FUNCTION.

BY ERNEST BULMER, M.D., M.R.C.P. EDIN., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM.

ABOUT 18 months ago my experiences of this test e published, and they were distinctly unfavourable, a number of normal cases gave abnormal results, l even in cases of definite liver disease 20 per cent. the readings were at variance with the clinical dence.[1] For this series a bromsulphalein was de in this country, on the lines of statements made Rosenthal and White in the *Journal of Pharma- gy and Experimental Therapeutics* in 1924. It was sequently found that this dye differed in certain rticulars from that of Rosenthal and White, and consequence did not give results representative of r efficiency. Bromsulphalein is, at any rate at sent, a proprietary obtainable only from Hynson, Westcott, and Dunning, of Baltimore. I am indebted to them and to Dr. White for having sent me the dye for use in this new investigation. The results are set out below, and they are a contradiction of the previous ones published.

A review of the history of the test was given at some length in a previous paper,[1] and only a few salient points need to be repeated. Bromsulphalein or phenoltetrabromphthalein sodium sulphonate was prepared by White; it is a whitish powder very freely soluble in water, and it can be given with impunity by intravenous injection in a concentrated solution. It is non-irritant, and in ordinary doses absolutely non-toxic. Normally the dye is seized by the liver, and the majority is excreted in the bile, traces only appearing in the urine. The rate of disappearance of the dye from the blood serum is important—after five minutes 20–50 per cent. remains in the blood, whilst at the end of half an hour there is none at all or a mere trace. It was argued that if the liver were damaged it would remove the dye with less rapidity from the blood after injection, and that the degree of retention of dye in the blood stream would give an indication of the degree of liver damage; the originators of the test, Rosenthal and White,[2 3 4] denied that it had any dependence upon biliary permeability.

Technique.

The patient is weighed and the dosage is calculated on a basis of 2 mg. of the dye per kilo body-weight—the body-weight of the patient in pounds divided by 55 will give the exact quantity in cubic centimetres of the 5 per cent. solution employed. It is injected slowly into one of the arm veins. Thirty minutes after the injection a sample of blood is withdrawn, preferably from the opposite arm, and in cases of early liver disease it may be necessary to take a sample after five minutes. After the blood has coagulated it is centrifugalised and the clear serum is pipetted into two small test-tubes. To one of these is added one or two drops of a 10 per cent. solution of sodium hydroxide to bring out the colour of the dye, and to the other tube a drop of 5 per cent. hydrochloric acid to clear the serum of any hæmolysis. The amount of dye in the serum is now estimated by direct comparison with a series of standards, using a simple comparator box in the usual way. The standards may be prepared by adding 4 mg. of the dye to 100 c.cm. of water that has been alkalinised with 0·25 c.cm. of a 10 per cent. solution of sodium hydroxide. This represents the 100 per cent. standard, and a series is prepared ranging from 5 per cent. upwards by dilution with alkaline water. In practice it is much simpler to employ the series of non-fading standards prepared by Hynson, Westcott, and Dunning. The 100 per cent. standard represents the amount of the dye that would be present in the blood stream if none were removed; it is thus an arbitrary standard calculated on blood volume.

Clinical Findings.

(*a*) Rosenthal and White[4]:—

	Cases.	Retention expressed in percentages after 30 minutes.
Non-liver	25 ..	0 or a mere trace.
Obstructive jaundice ..	5 ..	97, 96, 90, 35, 30.
Cancer of liver	2 ..	99, 20.
Catarrhal jaundice ..	3 ..	75, 50, 35.
Arsphenamine jaundice ..	2 ..	47, 22 (after 15 min.).
Biliary cirrhosis	1 ..	45.
Portal cirrhosis	3 ..	?, 22, 17.
Syphilitic cirrhosis ..	1 ..	3.
Pre-eclamptic toxæmia ..	1 ..	30.
Acute cholecystitis ..	1 ..	10.
Chronic „ ..	1 ..	5.

(*b*) Friedenwald and Armstrong[5]:—

Catarrhal jaundice ..	2 ..	28, 36.
Cirrhosis of liver	5 ..	50, 40, 0, 5, 18.
Cancer of liver	9 ..	20, 45, 10, 36, 5, 8, 24, 18.
Syphilis of liver	1 ..	0.
Cancer of pancreas ..	2 ..	32, 24.

Non-liver Cases.—Cancer of stomach, 5; chronic cholecystitis, 11; achylia gastrica, 7; hyperchlorhydria, 10. All of these showed no retention.

(*c*) Rouillard [6] :—

Non-liver	25	..	No retention or a mere trace.
Cancer of liver	1	..	99.
Cancer of pancreas ..	1	..	97.
Suppurative cholecystitis	2	..	95, 90.
Catarrhal jaundice ..	3	..	75, 50, 30.
Arsenical jaundice ..	1	..	47.
Cirrhosis	3	..	45, 22, 17.
Calculous cholecystitis ..	2	..	10, 5.
Syphilitic cirrhosis ..	1	..	3.

(*d*) *Personal Cases.*—The technique used was that described above, and the results are expressed as the percentage retained after 30 minutes so that the figures are strictly comparable to those in the accompanying tables.

Non-liver Cases.

Gonorrhœa	9	..	5 ; three=0 ; five=trace.
Dyspepsia	2	..	5, 0.
Progressive muscular atrophy	1	..	0.
Hysteria	1	..	0.
Lymphadenoma	1	..	0.
Tb. abdomen	1	..	0.
Convalescent nephritis ..	1	..	5.
,, pneumonia ..	1	..	0.
Cancer of breast	1	..	Faint trace.
Slight cerebral thrombosis	1	..	Faint trace.
Normal	3	..	Trace, 0, 0.
Aortic incompetence ..	1	..	0.
Progressive bulbar paralysis	1	..	0.
Pleural effusion	1	..	5.
Pericarditis (convalescent)	1	..	0.
Asthma	1	..	0.

Liver Cases.

Portal cirrhosis	7	..	0, 25, 28 and 30, 7, 0, 25, faint trace.
Obstructive jaundice (cancer of pancreas).	4	..	105, 105, 40, 30.
Catarrhal jaundice ..	2	..	0 (convalescent, conjunctivæ just icteric), 53.
N.A.B. jaundice	5	..	0 (7 months after). 50 (22/6/27), 5 (29/6), 0 (6/7). 0 (15/7), 5 (21/7), conjunctivæ just yellow. 15, jaundice rapidly clearing. 70 (18/2/28), 105 (23/2).
Syphilitic jaundice (secondary stage).	1	..	75 (2/3/28), 10 (28/3) after a course of N.A.B., much less yellow.
Cholecystitis	2	..	15, 10 (faintly subicteric).
Obstructive biliary cirrhosis following cholecystectomy—rigors, jaundice, enlarged liver and spleen.	1	..	11/8/27 : 25. 3/9 : 10—less jaundice. 7/9, drainage of common duct ; almost died of cholæmia. 29/9 : 10.
Cardiac liver — moderate jaundice.	1	..	18.
Non-calculous cholangitis with intermittent painless jaundice for 2 years.	1	..	30 (11/8/27), 30 (3/9).
? Pancreatic calculus ..	1	..	0.
Acholuric jaundice with cholelithiasis.	1	..	12.
Tested during N.A.B. treatment—no symptoms.	2	..	10 (last injection 14 days before) ; 0 (2 days before).
Congenital chorea ..	1	..	0.
Primary cancer of liver without jaundice.	1	..	5.

During the administration of choriotrope three cases were tested :—

1. 35 c.cm. given, the last dose being 18 days before the test and followed by jaundice—now clear. 40 per cent.
2. 15 c.cm. given, the last one month before the test. 0 per cent.
3. 33 c.cm. given, the last ten days before the test. 0 per cent.

Two of these cases require a little amplification ; the fifth case of N.A.B. jaundice showed a very much greater retention after a period of treatment than before it (105 per cent.) ; she was clinically improved, however. A possible explanation is that the injection was given into the same vein from which blood was later withdrawn ; it is probable that the sample was thus accidentally contaminated with dye from the skin or from the vein. One of the cases of cirrhosis was admitted to hospital for a painless hæmatemesis, a bromsulphalein test showed merely a faint trace of dye after half an hour ; at operation later a definite early cirrhosis of the liver was found. There was no reason to suspect a sufficient degree of functional incompetence to produce any dye retention.

Conclusions.

1. Normal cases and those without any liver le showed a retention of 5 per cent. to a mere trac even no dye at all.

2. Cases of liver disease showed a retention w probably represented fairly accurately the degr liver damage or functional impairment ; 100 per retention means that no dye is removed from blood, and a retention of, say, 50 per cent. w mean that the liver was 50 per cent. incompe and so on.

3. The test is one of liver function and no biliary permeability ; this is proved by the fact many of the cases of complete obstructive jau did not give a 100 per cent. retention.

4. The test is safe, simple, and it appears to b best one we have.

Finally, the writer would like to express his th to the honorary medical and surgical staff of General Hospital, Birmingham, for their kindne giving him access to their cases.

C.B. = County Borough. B. = Borough.

Health resorts, by attracting as residents old peopl invalids, swell many of their death-rates. Thus the death from all causes of Tunbridge Wells and Leamington Spa, standardised for age and sex constitution of the popul become 11·5 and 10·74 respectively. The contrast betwee infant and neonatal mortality-rates of the three health r shown above is very striking.

Grimsby.

Dr. B. C. Stevens reports that the muni maternity home, with ten beds, erected on council's housing site at Nunsthorpe, was opene the admission of cases on Sept. 19th. Dr. Ste thinks it will soon need enlarging. Seven notifica

d six deaths from encephalitis lethargica were corded during the year. The notification of tuberlosis is still not nearly so complete as it might be. the 105 total deaths, 24 were of cases not eviously notified, and only 29 lived for six months er notification. Insufficient institutional accomodation has been some excuse for incomplete tification in the past, but a scheme now under nsideration for the extension of treatment facilities ght to meet this objection. Another feature of the rk that requires development is the examination contacts. At present the staff is insufficient for e visitation of homes for this purpose, and home itation is considered by Dr. Stevens essential for e full development of examination of contacts. combined clinic supplies artificial light treatment for e dispensary, the infant welfare centres, and the nools. "On the whole the results have been very couraging and have amply repaid the expenditure." e total cases treated at the V.D. clinic during the t six years have been 1206, 827, 437, 465, 480, and 3, and the defaulters—that is, those who ceased to end before being cured—for the same years mbered 547, 479, 184, 93, 89, and 79. Dr. Stevens vocates the establishment of a centre where persons, o have exposed themselves to the risk of contracting nereal disease, can be immediately disinfected by skilled orderly. He thinks a capital expenditure £100 or a weekly expenditure of £4 would be ample the purpose, and that such a scheme would save ney by lessening the need for treatment. The ses of the six maternal deaths were puerperal sis 2, antepartum hæmorrhage 1, post-partum morrhage 1, and eclampsia 2. The midwives lise the importance of the antenatal supervision t upon them and are referring more cases to the enatal clinic. The new cases at this clinic numbered 5, the total births being 1624.

West Bromwich.

Dr. W. Stott reports that in September it was cided to reorganise the health visiting staff and to lace the part-time nurses from the district Nursing sociation by six newly appointed health visitors, o began their duties on Nov. 1st. The area of the ough is now divided into eight districts, and one se is responsible for all the health visiting services each district. The medical staff has unfortunately n reduced from three to two. As a result it is possible for the doctor to examine all the children ught to the centres, and it is also impossible to dertake antenatal and postnatal work. The outnding feature of 1927 was the large number of ths of children from pneumonia, caused by the valence of measles, whooping-cough, and influenza ing the first quarter. Dr. Stott advocates provision the home nursing of measles, whooping-cough, l pneumonia, with hospital accommodation for ere cases, and he further suggests that the first es of measles or whooping-cough in children under 5 uld be made notifiable. The instruction to the lwives to do antenatal work is receiving attention, renders the provision of an antenatal clinic all more urgent. Seventy-five stillbirths were notified 1927 as against 58 in the previous year. There is, yet, no definite orthopædic scheme, no scheme for home nursing of children under 5, no minor nent clinic in connexion with the welfare centres, l no dental treatment included in the maternity l child welfare scheme. Of the 46 deaths from monary tuberculosis 10 were those of cases notified, and of the 8 non-pulmonary tuberculosis ths 6 were those of unnotified cases. The sanitary pector, Mr. H. H. Spears, after comparing the ults of last year's housing inspections with those de of the same houses six and seven years previously, ls "that notwithstanding the general housing ivities of the council, conditions as regards two-nily occupation and overcrowding in such houses re in no wise improved." The new houses erected ing the year numbered 466 and included 286 muni-al houses. In a few outlying districts there are still some surface wells in use, and Dr. Stott refers to one used for the supply of three farms, which is liable to pollution by the overflow of the river. The opening of the new Health Department building in December will greatly facilitate the work.

Carlisle.

Dr. Joseph Beard says that the report calls for little comment and that the sanitary condition of the city generally may be said to be good. Out of 20 samples of fresh cow's milk two contained tubercle bacilli, resulting in the eliminiation of one milch cow from the city byres and of two outside cows from a herd in the Longtown area. The Ministry of Health have sanctioned 1728 municipal houses, 1540 "non-parlour" and 188 "parlour." Of these, 1394 have been completed and the remaining 334 were in course of erection at the end of the year. Dr. Beard complains that notification of tuberculosis is frequently so late as to be useless. During 1927 about 18 per cent. of the deaths were those of unnotified cases. A further 8 per cent. of the deaths occurred within one week of notification, while only 37 per cent. survived notification by more than three months. During 1926 the town clerk drew the attention of the medical men of the city to this failure to notify. The register of cases was completely revised during the year and now includes 145 males and 141 females of the pulmonary type and 46 and 47 respectively of the non-pulmonary type. This gives a total of 379, or about six times the average annual deaths during the last six years. Considerable difficulty is experienced in obtaining a satisfactory examination of contacts, but there is some improvement with regard to children. During the year the practising midwives attended 382 confinements and sent for medical help in 120, or more than 30 per cent. of their cases. The antenatal clinic was attended by 185 mothers who paid from three to four visits each; the total births numbered 1037.

Eastbourne.

Dr. W. G. Willoughby reports that 405 houses were erected during the year, of which 198 were municipal and 45 subsidised houses erected by private enterprise. No houses at low rents have been built recently except by the municipality, but houses at as low a price as £700 have been built for sale. The council assisted the private purchase of houses in 78 instances during 1927, making a total of 260 houses so dealt with. The temporary army hutments have been reduced from 188 tenements to 36 and the last 36 tenants are difficult to deal with, but "it is time that these huts should be totally demolished." The lowest rents for municipal "non-parlour" houses are 14*s.* 6*d.* weekly. The total of municipal houses occupied and planned is 723, but building for yearly needs must go on, says Dr. Willoughby, and particularly for those who canont afford the rent mentioned. Of the 764 applicants for new houses 90 have a whole house at present, 99 are newcomers, and 109 live outside the borough. Of the remaining 466, who have been in the borough more than five years, 78 have no child, 200 have one child only, and 89 have at least three rooms each. Dr. Willoughby estimates that there are at least 200 to 250 good tenants in a difficult position. There is too much sharing and subletting of houses, and many of the applicants would like a smaller house at a lower rent. Some of the municipal tenants have caused overcrowding by subletting. The municipal maternity home (ten beds) has been improved by the provision of extra accommodation for the staff and of facilities for antenatal work. The orthopædic clinic is run by a voluntary association for whom the local authority provides a consultant. An enclosure on the sea front, in connexion with it, allows sun treatment to be provided for children in the summer. Dr. Willoughby states that the regulations for the protection of meat have almost no practical effect owing to the restrictions involved. The majority of meat vendors object to sheltering the meat behind closed windows. Dr. Willoughby disagrees with those who favour the shortening of the stay of scarlet fever

patients in hospital. The revision of the tuberculosis register has reduced the cases to 318 which is about seven times the tuberculosis deaths for 1927. The rainfall for the year was 38·22 in. The sunshine record, 1698·8 hours, was the fourth highest recorded in the United Kingdom, excluding the Channel Isles and Scilly Isles.

Tunbridge Wells.

Dr. F. C. Linton says that apart from a sharp outbreak of influenza in February involving temporary school closure and causing many deaths amongst old persons, there was no notable outbreak of infectious disease during the year. The municipality works chiefly by subsidising voluntary institutions. Since April 1st, 1928, an agreement has been made for the treatment of children by massage, exercises, electricity, &c., at the clinic established at the general hospital. The district Nursing Association is subsidised for the home nursing of children and for the provision of a nurse-midwife in Rusthall. Payment is made by fees to various hospitals for the treatment of tonsils and adenoids. An arrangement has been made with the maternity home for the admission of municipal cases and three cases were sent in in 1927 where the mother's home environment was unsatisfactory and her circumstances needed financial aid. A chart shows that diphtheria was exceptionally prevalent from 1896 to 1900 and again from 1911 to 1915. Dr. Linton argues from these figures that the disease should be rife from 1926 to 1930 and in accordance with his prediction the notifications rose to 42 in 1927, after an average of about 12 for the four preceding years. There was only one death. The school report shows that the question of an open-air school for 40 children has been advanced a stage further by the raising of £1000 by voluntary contributions. Dr. J. A. Walker Wood began work as aural surgeon in the schools in April, 1927. The rainfall was 40 in. and the hours of bright sunshine 1527⅔.

Leamington.

Dr. W. L. Goldie reports that the baths have been rebuilt and now compare most favourably with those of any spa in the country. A new scheme of filtration has been installed for both the men's and women's swimming baths. The total number of council houses was brought up to 286 by the erection of 83 during the year. There were 12 subsidised private enterprise houses. The "Leamington Slum Clearance" Company built eight houses at Lillington which were intended to be let at an inclusive rental of 5*s*. a week, but were ultimately let at 10*s*. An agreement has been made with the Warneford Hospital for the subsidisation of three maternity beds. Mr. G. C. Alderson, who is in charge of the obstetric department of this hospital, conducts an antenatal clinic for the patients seeking admission to the hospital, and he has been appointed specialist for the purpose of the Puerperal Fever Regulations. The rainfall was 28·84 in. and the record of bright sunshine 1121·7 hours.

Colchester.

Dr. W. F. Corfield gives a table, which shows that 24 of the 35 infant deaths were due to congenital debility and premature birth. He hopes that the work of the antenatal centre begun in March, 1928, will help to reduce this figure. The deaths of children during the first year of life numbered 35, during the second year 14, and of those from 2 to 5 years 13. An effort is being made to find suitable premises for a maternity home, but so far unsuccessfully. The orthopædic clinic is doing good work and treated 17 infants as compared with 9 in the previous year. A difficulty has arisen with the local division of the British Medical Association with regard to the appointment of a consultant for the purpose of the Puerperal Fever Regulations. During the year 192 subsidised houses were built, 106 municipal and 74 by private enterprise. Reports of overcrowding are still received and there is need of accommodation for the poorest working-class families. Unfortunately a large number of families have to live in two rooms or even one room owing to the cost of housing accommodation. During the p years there has been much building of new houses the outskirts. This is being now followed by t extension of water mains and sewers, which sho ultimately enable shallow wells to be closed a cesspools to be abolished. During 1927, howev 19 new cesspools and 7 new wells were construct About 550 " hand-flushed " closets have been provic with a water-supply during the last three years.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Aver. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found o routine examinati requirin treatmen
Northampton C.B.	12,352	11,107	3,432	7,687	18·7
Bournemouth	7,984	6,796	2,160	3,952	14·0
Hull	47,517	38,614	17,075	34,719	15·8

* Excluding uncleanliness and dental defects.
C.B. = County Borough.

Northampton.

It would, we think, be admitted that the extent the facilities for preventing and treating child defect and disease is a fair measure of the inte taken in child hygiene by any community. Jud by this standard Northampton comes out badly, in this county borough even the routine inspecti cannot be overtaken by the school medical staff, much of the value of their work is necessarily l Dr. Stephen Rowland, in his introduction to the re by Dr. J. H. Mason, says he does not think that two sessions per week now given by the assist tuberculosis officer will be sufficient to keep pace w the work; he does hope, however, that the arre in dental treatment will be made up by the sec dentist now appointed. Dr. Mason, who until October carried out the school medical work sin handed, draws attention to the large number (246 delicate, anæmic, and debilitated children who wo benefit by the régime of an open-air school. Rowland is " not convinced that the so-called ' op air school ' is much in advance of the latest element schools opened in Northampton." He does describe the conditions of these new schools, bu would seem that a properly constituted open school, with a specially designed curriculum, wh there is fuller medical supervision, extra rest, suita meals, and out-of-doors lessons and games, is m suited to the needs of a delicate child than even most modern elementary school where the curricul and routine work are arranged for the average heal normal child. It is often the endeavour to keep p with his more lusty fellows that pushes the delic child over the brink of definite ill-health. Dr. Ma describes the work done in Wellington-place Spe Mental Defective School, opened in 1907, and su vised from its inception by Miss Longland, who acts as secretary to the committee of volunt workers which looks after the welfare of past pu In all, 234 children have passed out, of whom 24 dead, 101 are either in institutions or not in w and 109 are partially or wholly self-support Whatever the future may hold in the way of prevent or of treatment of mental defectives, it is certain t the discipline, interest, and self-respect instilled by simple manual occupations at present taught in special schools is well worth the cost, for if tl unfortunates are left unheeded they become a gre burden on the community.

Bournemouth.

Dr. T. S. Stirling remarks that the general wor medical inspection is progressing satisfactorily, notes a continued improvement in the standar

onal hygiene due to the work of the school nurses, d by lending out, if required, of special combs with aflet of instruction. The dental work has been iently carried out, but there is still a long list ting treatment, and the pre-school child must not orgotten. Dr. Stirling says that in this, as in many ie other defects and diseases of childhood, preven- treatment should be attempted at an earlier age ; with a suitable physiological diet in infancy, will n the prevalence of dental caries in school lren. The idea of the special class for backward lren was to return these children after a course of 12 months to their own school with a reasonable ctation of making normal progress ; this has not realised, though the children have derived fit, especially physically. Probably there are in class all three types of retarded children—namely : The true backward, that is those who have merely education time through being handicapped by ise or physical defect, and thus need a recovery ; (2) the true dull, those who are mentally and better with concrete material, and thus need ndicraft class ; (3) the true mental defective, tally lacking in all kinds of intelligence, needing ing in concentration, stabilising in temperament, some degree of care, control, or supervision in -life. The formation of even this one experimental is of value, especially as it is a small one with 15 children, so that an energetic teacher will to group the children for herself. It is, however, ettable that there are no special schools and icularly no open-air school, for there are in rnemouth 246 delicate children with whom results d be obtained comparable with the splendid record iany similar towns.

Hull.

r. W. Allen Daley deals with important schemes of ganisation, details of which are given by his chief istant, Dr. J. Morrison. Routine examinations have eased from 15,526 in 1926 to 17,075. The standard narking for defects has been made slightly more igent, to bring it into line with that of other iorities ; thus the percentage of defects this year unts to 15·8 compared with 10·5 in 1926, although actual numbers of defects have probably not eased. Special inspections show a great increase he result of the new scheme by which teachers children to the medical officer at a school clinic, ead of waiting for a routine visit to the school. tment at the clinics has been greatly expanded 00 minor ailments were treated this year as nst 3281 in 1926. X ray treatment for ringworm in future be given by the two newly appointed ologists. In dental treatment there has also been organisation of the scheme, including an extension nclude the 5-year-old group, increased general ities with the appointment of an additional ist, and the elimination of casual cases, which are unsatisfactory. There are, further, some new rities at the clinic ; those of the aural surgeons, T. Ritchie Rodger and Mr. R. R. Simpson, whose rt opinion is found so valuable in cases of tonsils adenoids, and of the orthopædic clinic just started r Mr. R. B. Blair. This orthopædic clinic deals with cases referred by other departments—the ral public health, the tuberculosis, and the rnity and child welfare.

ne planning of this work as regards school-children temporarily upset by an epidemic of acute myelitis affecting 22 children over 5 years of age, over 70 below that age. Of the older group one during the attack, in four cases the paralysis ed up, and in 17 there remained varying degrees sability, though, as usual, there was some tendency rds recovery. The younger group is not similarly ribed, but it is certain, as Dr. Morrison says, that epidemic will leave lasting traces among the school- lren of future years. The action taken illustrates well the advantages of coördination. Many of the ms were isolated and treated in the City Hospital ; were examined by the school orthopædic surgeon, who prescribed the treatment to be carried out both in hospital and after discharge. Later they were taken to the Park Avenue School for physically defective children, where splints were applied when necessary, and appointments made for massage, electricity, or remedial exercises at the orthopædic clinic. In the case of private patients, letters were sent to the doctors offering facilities for treatment at the orthopædic clinic, which was in the majority of cases accepted. Two recently appointed orthopædic nurses carry out this treatment at the clinic under the supervision of the surgeon. Minor postural deformities are reported to the organiser of physical training for special exercises to be given at school.

Another important step has been taken in the new practice of examining mentally all the children admitted to the craft classes, thus raising these classes to their proper function of dealing with the concrete minded children, who are intelligent enough but not literary, instead of allowing these classes to become the dumping ground for all types of retarded and defective children. The whole report shows evidence of a highly efficient staff working with an enlightened local authority.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 4TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 126 (last week, 149) ; scarlet fever, 1461 ; diphtheria, 882 ; enteric fever, 277 ; pneumonia, 526 ; puerperal fever, 39 ; puerperal pyrexia, 85 ; cerebro-spinal fever, 7 ; acute poliomyelitis, 2 ; acute polio-encephalitis, 2 ; encephalitis lethargica, 28 ; dysentery, 7 ; ophthalmia neonatorum, 139. No case of cholera, plague, or typhus fever was notified during the week.

A large proportion of the cases of enteric fever were notified in London and the home counties, viz. : London 87 (of which 26 in Kensington, 17 in Wandsworth) ; Buckingham, 4 ; Essex, 5 ; Hertford, 7 ; Kent, 7 ; Middlesex, 25 (of which Ruislip-Northwood 6) ; Surrey, 97 (of which Beddington and Wallington 24, Epsom 23, Sutton and Cheam 10, Epsom Rural 18). The 277 notifications included 175 cases of paratyphoid fever, of which 60 were notified in London, 83 in Surrey, and 11 in Middlesex.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on August 7th–8th was as follows :—Small-pox, 17 under treatment, 1 under observation ; scarlet fever, 1706 ; diphtheria, 1681 ; enteric fever, 72 ; measles, 263 ; whooping-cough, 187 ; puerperal fever, 14 (plus 9 babies) ; encephalitis lethargica, 71 ; poliomyelitis, 2 ; "other diseases," 15. At St. Margaret's Hospital there were 17 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (2) from enteric fever, 21 (2) from measles, 2 (2) from scarlet fever, 36 (4) from whooping-cough, 29 (5) from diphtheria, 50 (14) from diarrhœa and enteritis under two years, and 16 (4) from influenza. The figures in parentheses are those for London itself.

The fatal case of enteric fever outside London was reported from Edmonton. Of the 19 fatal cases of measles outside London, 6 were reported from Liverpool and 3 from Newcastle-on-Tyne. Belfast reported 5 in the same week. Of the 32 fatal cases of whooping-cough outside London, 7 were reported from Birmingham, 4 from Manchester, and 3 from Liverpool. The deaths from diarrhœa showed no increase.

The number of stillbirths registered during the week was 295 in the great towns (corresponding to a rate of 41 per thousand births), including 43 in London.

THE PROCEEDS OF HOSPITAL FÊTES.—During the last eight years, Hendon Cottage Hospital has received £7287 as the proceeds of an annual fête. This year's event resulted in a profit of £1050.

Reviews and Notices of Books.

TRAUMA AND COMPENSATION IN OBSTETRIC AND GYNÆCOLOGICAL CASES.

By DOUGLAS MARSHALL LINDSAY, M.D., F.R.F.P. & S. Glasg., Senior Assistant Visiting Surgeon, Royal Samaritan Hospital, Glasgow. London and Edinburgh: William Hodge and Co., Ltd. 1928. Pp. 172. 7*s.* 6*d.*

THIS book is a useful contribution to a subject either cursorily dismissed or not considered at all in obstetric and gynæcological treatises. Yet, as the author points out, application for damages is very common among women, and real or fancied injury to a pregnancy offers "a good background for the staging of a case before an impressionable jury." The number of cases quoted from Dr. Lindsay's own experience serves to show both the frequency of claims of this kind and the solid foundation of practical knowledge on which this book is built. The instructions as to methods of examination, the way to record findings, and the precautions to be taken when giving an opinion are excellent.

Concerned, as it is, with a very special side of obstetric and gynæcological practice, this book may not appear to be of general interest, but even a superficial glance reveals many points that have a much wider application than its title suggests. It contains, for example, an excellent review of the diagnosis of pregnancy in which the various symptoms and signs are weighed and the value appraised of those that are of use in estimating the stage that the pregnancy has reached, and in determining the life or death of the fœtus in utero. One sign in the diagnosis of pregnancy, that form of external ballottement known as "dipping" has been overlooked. To many it is the most certain and quickest method of differentiating the pregnant uterus from other cystic swellings at or about the umbilical level and before fœtal parts can be distinctly recognised.

Dr. Lindsay makes a very definite statement that trauma is never a causative factor in the production of a neoplasm; his views on this question are diametrically opposed to those expressed by Dr. Janet Lane-Claypon in regard to injury as an ætiological factor in mammary carcinoma (Ministry of Health Report No. 32). Sarcoma of bone appearing after injury he regards as "having probably been the precursor of the fracture." Whilst refusing to consider a traumatic cause for pelvic growths, simple or malignant, he gives full consideration to the possibility of their being adversely affected by injury, as by the occurrence of torsion, rupture, necrosis, and infection.

The volume has closed a distinct gap in gynæcological literature, and will be found exceedingly helpful to those who have to make frequent appearances in the law courts to give a medical opinion in those compensation cases or actions for damages in which possible pelvic injury to women is in question. The author's experience in obstetrics and gynæcology, and as assistant to the Professor of Medical Jurisprudence in Glasgow, makes his advice of particular value in such cases.

EXPERIMENTAL EMBRYOLOGY.

By THOMAS HUNT MORGAN, Professor of Experimental Embryology in Columbia University. New York: Columbia University Press. 1927. Pp. 766. 37*s.* 6*d.*

THE introduction of experimental methods, chemical, physical, and physiological, into embryology is an important development. Although such methods have been applied for over 40 years by a few scattered workers and have yielded fruitful results, these results have so infrequently been brougl the general notice that those not intimately fan with the work have difficulty in correlating them in appreciating their full significance. Prof. Mor book, which is a complete and critical surve the important experimental researches, wil welcomed. Moreover, it will appeal to a section of scientific workers than did the embryology books, which described the buildin of evidence in a chain of pictures revealed by microscope. The experimentalists have called play methods more proper to the chemical and t physiological laboratories. This change of ou has revealed new lines of attack on the prol presented by each stage in the complicated proce development. The changes which take plac the process of fertilisation of the egg are vast complex. Already the amount of fruitful ex mental research relating to that incident a including the questions of the activity, chemo and agglutination of spermatozoa, the fertilisa membrane and its functions, selective fertilisa cross-fertilisation, and polyspermy, exhausts chapters, or over 100 pages of the book.

The remaining six hundred odd pages are occ with the questions involved in the change cytoplasm prior to cleavage of the cell, and in movements of groups of cells following clea Such matters as growth, reflex actions, and tropl movements of larvæ, sex determination, embr grafting, the influence of environment on the dev ment of the embryo, and the source of energ development, are promised for a future volume. investigations relating to each section are rec more or less in their chronological order. The aut conclusions, which are restrained and conservativ inserted into the text at intervals none too freq His obvious reluctance to introduce specul matter might indeed have been modified to extent of furnishing short summaries at the e each section, for an historical account of such co work must necessarily in places be disjointed, c for effort on the part of any reader anxious to u stand the trend and significance of the pro made. However, since Prof. Morgan provides 2000 references to works on experimental embry and sets forth concisely and lucidly a descri of practically every important piece of work has been done on the subject, no one need comp

To workers in every branch of biology wh seeking for a new line of research this book sl provide a mine of inspiring suggestions.

ENDOCRINE DISEASES.

Endokrine Krankheiten. By Prof. Dr. CURSCHMANN, Direktor der medizinischen versitätsklinik zu Rostock I.M. Dresden Leipzig: Theodor Steinkopf. 1927. Pp. R.M.8.5.

THE series of monographs to which this vo belongs is designed to give a practical survey o various domains of medicine. Prof. Curschm Endocrine Diseases can claim to have fulfilled object. Controversial matter has been almost en ignored, and where theoretical interpretation is far from clear the author has contented hi with giving the facts and a short allusion t difficulties. No condition associated with di of the endocrine system seems to have been om The method of dealing with any particular gla to give first a short description of its anatomy physiology, then a detailed account of the sympt tology, pathogenesis, prognosis, and treatmer diseases associated with it. Certain rare meta disturbances of uncertain origin are included. instance, a section is devoted to what is te endogenous cachexia. This condition is conc as the clinical antithesis to endogenous obesity. author differentiates it from a masked hyperthy

, in which there are no eye or circulatory dis-
ances, and from wasting of hypophyseal origin
nmond's disease). The metabolic rate is not
ed nor is the protein metabolism increased, as in
ves's disease, and yet there occurs a progressive
in weight until the patient becomes a veritable
eton. The author claims that by psycho-
apeutic measures the appetite of these cases can
o stimulated that the weight increases. By doses
nsulin up to 20 units daily weight can also be made
ncrease, but the writer denies that the condition
n any sense of the word a "hypo-insulinism." In
v of the most recent work on mongolism it is
nge to find this condition included in this mono-
h; indeed, the author himself, having described
malformation, concludes that there is no evidence
n endocrine dyscrasia. An interesting point in
treatment of exophthalmic goitre is emphasised—
importance of diet. This is a revival of the old
v of Blum that the diet should consist of foods
aining a minimum of tryptophane, which is the
nical basis of thyroxin. Meats, milk, cheese,
s, and wheat are rich, whilst maize, rye, potatoes,
fruits are poor in this substance. However,
e one of the main objects of treatment is to
stablish nitrogen equilibrium in the exophthalmic
ent, it would not be very easy to avoid those
is which are here condemned.
he section on diseases of the sex glands has been
ten by Dr. F. Prange and is well illustrated.
space allotted to details of treatment in this
k is rather scanty, but the general principles
h should guide the management of the patient
made clear.

: CLINICAL EXAMINATION OF THE LUNGS.

Second edition. By E. M. BROCKBANK, M.D. Vict., F.R.C.P.; and ALBERT RAMSBOTTOM, M.D. Vict., F.R.C.P. London: H. K. Lewis and Co., Ltd. 1928. Pp. 112. 5*s*.

HIS book was written for students, and is intended
utline the methods of examining the chest. It is
sufficiently detailed to appeal to the post-graduate
lent, who would require more detail. After a
f chapter on physiology and anatomy, five
pters are given up to a discussion of the symptoms
physical signs of pulmonary disease, the authors
owing the orthodox order of inspection, palpation,
ussion, and auscultation. The last chapter deals
physical signs of common pulmonary diseases,
this is too sketchy to be of real value even to
lents. Very little space is devoted to each
ase, such a variegated condition as new growth
ediastinum, lung, and pleura being dismissed in
lines. The reader is told that X ray examination
useful aid to diagnosis in various conditions,
it is not made clear in what way it may help.
he end of the book are eight X ray plates illus-
ing a normal chest and various pathological
litions. If the volume is regarded as a con-
ent and clear, but not exhaustive, account of
sical signs and symptoms in diseases of the chest
ill prove a useful addition to the students' library.

TERIOLOGY.

Handbuch der Pathogenen Mikroorganismen. Third
dition. Edited by KOLLE and WASSERMANN.
Revised and enlarged with the assistance of
W. KOLLE, R. KRAUS, and P. UHLENHUTH. Jena:
Gustav Fischer; Berlin and Vienna: Urban and
Schwarzenberg. 1928.

HE new edition of Kolle and Wassermann's well-
wn text-book upon bacteriology is now in process
aking its appearance in instalments; up to the
ent time 12 parts have been received, repre-
ing portions of the ten volumes of which the
k will ultimately consist, none of which has yet
eared in its entirety. The wealth of detail is
ter than that given in any other work on
eriology with which we are acquainted; the article on plague, to take a single example, by Dieudonné and Otto, occupies 223 pages and is superbly illustrated. The work is already firmly established as a mine of information upon all the ramifications of bacteriology and immunity. Amongst the subjects dealt with in the parts which we have received are plague; Asiatic cholera, which comprise the whole of one part, a matter of 178 pages; glanders; rinderpest and other special animal infections; diplococcal infections; and a large part of the subjects of general bacteriology, immunity and serology. When complete the book will form a standard book of reference and, meanwhile, has the advantages of a series of monographs, each contributed by an authority in his own special sphere.

INVESTIGATION OF THE CONCENTRATION OF LACTIC ACID IN BLOOD AND URINE UNDER PHYSIOLOGIC AND PATHOLOGIC CONDITIONS.

By OTTO JERVELL. Acta Medica Scandinavica, Supplementum XXIV. Oslo: Nationaltrykkeriet. 1928. Pp. 135.

THIS book consists of a collection of researches carried out during the last four years by the author, partly at the Physiological Institute of the University of Oslo, and partly at the Oslo Municipal Hospital. It is divided into three parts: the first, an introduction, deals with previous work and methods of analysis, the second with lactic acid under physiological conditions, and the third with the concentration of lactic acid in the blood in various pathological states. In the first part some six pages are devoted to a very brief review of the work, beginning with that of Fletcher and Hopkins in 1907, which deals with the rôle of lactic acid in the metabolism of carbohydrates. Dr. Jervell then proceeds to describe the method used by him for the estimation of lactic acid in blood and urine. In the case of blood, the proteins are first precipitated by tungstic acid, as in Clausen's method, using 2 c.cm. of blood. The glucose, together with a part of the uric acid, is then removed from the filtrate by the use of copper sulphate and calcium hydroxide. The estimation is performed upon the filtrate from this precipitation by Hansen's method, which involves the oxidation of the lactic acid to acetic acid and carbon dioxide by a measured excess of potassium dichromate solution and sulphuric acid. The unused dichromate is afterwards estimated iodimetrically. When lactic acid in urine is being determined, it is necessary first to extract the lactic acid by means of ether, using Clausen's apparatus for this purpose. Tables are given showing that the mean error is approximately 5 per cent. In the second section, the lactic acid concentration of human blood during rest is first investigated. The average value of a series of determinations on four subjects is found to be 27 mg. of lactic acid per 100 c.cm. of blood, the extreme values found being 21 and 31·5 mg. per cent. The difference between the lactic acid figures of fasting subjects and those who have had a breakfast of bread and milk is shown to be negligible. Then follows an investigation of the lactic acid concentration in blood during muscular work, using a cycle-ergometer. In every case muscular exercise produces hyperlactacidæmia, the increase being greater in the first minutes of exercise than later. Large outputs of work (over 1000 kg. meters per minute) bring about a considerable increase of lactic acid concentration in the blood; on resting, this slowly falls off, reaching the normal value again in about half an hour. Mild exercise causes this falling off to be slightly more rapid. The hyperlactacidæma is due to a shortage of oxygen, and the oxygen debt calculated from the lactic acid present is approximately equal to that actually found. The urinary lactic acid after physical exercise may increase to 1 per cent., the excretion in the urine being increased by the administration of alkali.

The author then proceeds to investigate the lactic acid concentration of blood and urine in subjects

where impeded oxygen intake might be supposed to lead to hyperlactacidæmia. Examinations of 29 patients with heart disease, five of which were compensated, are quoted. In compensated heart disease the lactic acid concentration of the blood is normal, but it is frequently increased in cardiac insufficiency. In anæmia the lactic acid in the blood is found to be increased in a large proportion of the cases examined. Pneumonia and pulmonary tuberculosis may lead to increased lactic acid concentration in the blood. Fever does not increase the lactic acid content, but in spastic conditions hyperlactacidæmia is observed. In nephritis this is the case only where uræmia is present.

The book would be more readable if the sections had been planned to form a connected story instead of in a form resembling a series of publications in a scientific journal, but it represents a large amount of interesting work. A well-selected bibliography is included at the end of the volume.

DENTAL PROSTHETIC MECHANICS.

By D. M. SHAW, Curator of the Prosthetic Laboratories, Royal Dental Hospital of London. London: Edward Arnold. 1927. Pp. 373. 21*s*.

THIS book has been written for the dental student and for the laboratory mechanic, and the author expresses a diffident hope that it will interest the dentist as well. He rates his book too modestly. This is a most stimulating and original treatise on practical dental prosthesis. Mr. Shaw has had a wide experience as a teacher, and has also been active in research which has attracted attention from dentists and anatomists. He has not attempted to give a formal account of the steps in the construction of a denture, but rather to consider the various aspects of dental prosthesis and to comment on the underlying chemical, physical, and anatomical principles involved. This leads him into a consideration of many difficult problems which demand the close attention of the reader, but he does not neglect to mention practical tips which the laboratory worker will find useful. His views are not always orthodox, and the dentists who have given special study to dental prosthesis may find themselves in conflict with some of them; but they will not find it easy to dispose of his arguments. Among the sections to be singled out for special praise are those on the setting up of artificial teeth, articulators and metal-plate work. The preliminary chapter on the arrangements of the natural teeth is a useful contribution to an aspect of dental anatomy which has not received much attention.

The style in which the book is written is rather involved, and it is sometimes difficult to follow Mr. Shaw's meaning, but the effort is worth making, for the book shows real originality. It is well illustrated and excellently produced.

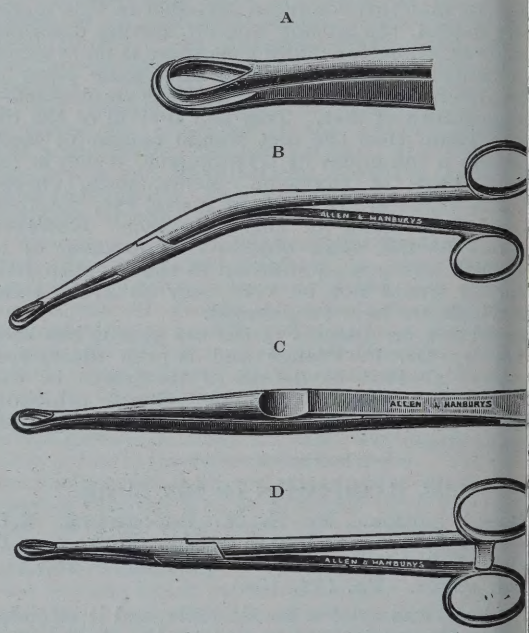
JOURNALS.

MEDICAL WOMEN'S INTERNATIONAL JOURNAL.—The May issue (Vol. I., No. 6) is given up entirely to the proceedings of the open meeting of the Medical Women's International Association held at Bologna from April 11th to 14th last. Summaries are given of all the 34 papers on the two subjects selected for discussion—viz.: (1) medical measures for the protection of children in various countries; and (2) diseases of the eye in relation to general medicine. The abstracts are printed in English or French, the journal being reluctantly restricted to these two languages on financial grounds. It is understood, however, that the Italian association of medical women is bringing out its own report of the proceedings, and the German association publishes its own monthly journal. The papers, even in summary, are well worth careful study, and it is a pleasant surprise to find an example of an international journal which does not contain typographical errors.

New Inventions.

IMPROVED FORCEPS.

SOME years ago when working out an instrum for holding that very friable organ, the tonsil, du dissection, I designed a grip which I believe to both new and of a fairly wide application in surg Its principle is to produce a ruck in the mate grasped by its blunt overlapping jaws (A), muc the way of the Army Regulation fastener for webl



straps. It is obvious that a grip of this sort will out less easily in flimsy material than one depends for its hold on piercing or crushing. original tonsil forceps (B) proved so popular th have had two other models made—a tissue forceps which is very useful for holding tuberculous gla cyst walls, and other "washy" tissues, and a b forceps (D) which I think will grip intestine r firmly and with less damage than anything el have ever tried.

The forceps are made by Messrs. Allen Hanburys, 48, Wigmore-street, W.

DENIS BROWNE, F.R.C.S. En

Reports and Analytical Recor

EUROSPA.

(S. R. TOOGOOD, 173, KING'S-ROAD, HARROGATE.)

EUROSPA is a cream-coloured powder which cl to possess the curative properties of the salts conta in the natural medicinal waters of Harrogate, B Wiesbaden, and Vichy. On analysis, the follo results were obtained:—

Moisture	6·10	per cent.
Matter, insoluble in water ..	9·16	,,
Matter, soluble in water ..	84·74	,,

The insoluble matter consisted of magnes phosphate and a little sulphur. The soluble ma comprised sodium sulphate (37 per cent.), magnes sulphate (16 per cent.), small amounts of potass salts, tartrates, and citrates, and traces of lithium chlorides. The sulphur (2·5 per cent.) probabl present as "potassa sulphurata." When dissolve water the solution was slightly alkaline and ha distinct odour of sulphuretted hydrogen.

THE LANCET.

ONDON: SATURDAY, AUGUST 18, 1928.

DETENTION OF MENTAL PATIENTS.

mental disease may be no more than transient, obviously wrong to begin its treatment by ıg steps which will permanently damage a nt's chances in the struggle for existence. yone agrees, therefore, that certification should last resort rather than the normal preliminary ental care, and the Royal Commission on Lunacy osed a form of machinery designed to give this iple effect. They recommended that cases iring institutional treatment should be differently ıged, according to whether the patients were untary" or "involuntary," and the medical ssion has cordially accepted their suggestion "voluntary boarders" should be admitted into al hospitals, licensed houses, nursing homes and e care on the strength of their written application. ıssion continues on the question whether such an cation justifies detention of a patient who objects e treatment, but for the moment our object is raw attention rather to the conditions under h he can in the first place be regarded as untary." The proportion of mental patients are ready to accept treatment is none too large, by the Commission's plan only these would be cted from legal intervention. It is true that intended reforms would permit of a modified of certification in cases where recovery is cted within six months, for if the prognosis is a patient would be treated under a Provisional tment Order without actual certification. But such an Order to be given the signature of a strate would be required, and it is far from asonable to argue that it is this intervention legal officer, with its attendant publicity, that ers the social stigma of insanity. Bearing this ınd, the Representative Body of the British cal Association, as we recorded on p. 240 of ssue of August 4th, reached the conclusion that Commissioners' reforms do not go far enough, gave its approval to an alternative plan, vhich the law's intervention would be reserved ases in which the patient, though capable of ion, definitely refused or resisted institutional ment. Under a scheme of this kind the luntary" boarders would include all those who e no categorical objection to being so declared, this would undoubtedly increase the number of le who would receive institutional care without ng been certified. Furthermore, the knowledge treatment could be got on these terms would urage the friends and relatives of a patient to him properly looked after at an early stage.

From the medical standpoint, therefore, the Association's proposal has much to recommend it; but there are certain obstacles to its being adopted. In the first place it may be observed that though reform of our lunacy law is inevitable, the prospect of it is by no means immediate. Sir FREDERICK WILLIS, lately chairman of the Board of Control, not long ago described the efforts of the Board to obtain amendment of the Lunacy Acts, and attributed their failure to a public apathy which refuses to be disturbed. The only noticeable symptom of any change in this attitude has been alarm at the restriction of liberty which the law already allows. This manifestation has taken the form of awarding fanciful damages against medical practitioners on the alleged ground of negligence in certification, and its result has been to make administration of the law more difficult, so that we approach a deadlock. What, then, will be the attitude of the public towards the British Medical Association's suggestion that a patient should be admitted to an institution without his consent, merely "on an 'Authorisation for Treatment' given by a relative or friend and supported by a 'recommendation' signed by two medical practitioners"? Will they not regard this as evidence of a desire on the part of medical men to be given powers altogether outside their proper province? Will they not think of it as another and flagrant attempt to strengthen the grip of the profession on mankind? The liberty of the subject is a national ideal, and one which no law reformer is likely or anxious to ignore. Though the law, in varying degrees at various stages of its history, has regarded the lunatic, the married woman and the infant as not fully capable of legal rights, Parliament would hardly dare to-day to decree that any of these classes of persons should be compulsorily detained in the absence of judicial proceedings.

One aspect of this proposal deserves more thought, perhaps, than it has yet received. If mental patients are to be placed in institutions without their express consent, on the decision of a relative or friend, recommended by two doctors, an unavoidable responsibility is bound to fall on the medical men concerned. Civil actions would certainly be brought against them from time to time, and it would not be at all surprising if lay juries were to make the most of these opportunities of registering a natural dislike of iatrarchy, or government by doctors. The profession is at the moment averse from increasing the number of vulnerable areas in its own skin, and is, indeed, anxious to disclaim a good deal of the responsibility placed upon it under the present Lunacy Acts. It is increasingly felt, moreover, that the further protection, which (to quote the Royal Commission) "should be given to medical men in the discharge of their professional duties in relation to insanity," can best be obtained by putting more of the onus of certification upon the representatives of the law rather than by taking it away from these officials. While no practitioner would wish to escape his proper liability to take due care, the British Medical Association's Representative Body has itself approved the principle that "the judicial authority, when it intervenes, shall accept responsibility for the detention of persons of unsound mind." And, oddly enough, this attempt to minimise medical responsibility is more likely to win public approval than the Association's plan for minimising legal intervention; though the former is made purely in the interest of the profession, whilst the latter is designed entirely for the benefit of mental patients.

RECENT FOOD INFECTIONS.

LONDON and the home counties have been unpleasantly aware, during the last week or two, of the prevalence of an infectious fever of the enteric group, some 90 cases being under treatment in the M.A.B. hospitals on August 14th. The disease has shown no respect for age or class, and has not been localised to any one area, although certain districts such as Kensington and Epsom have furnished most of the cases. On the whole the symptoms have been mild, the chief being headache and fever. In the average case there has been no vomiting and no diarrhœa, but rather constipation; the majority have shown rose spots in abundance, and a slightly enlarged spleen. Though a few cases have been severe and one death has been reported from Epsom, the outbreak cannot be regarded as really alarming. The organism responsible is *paratyphosus-B*, distributed it is presumed by food; while no particular comestible can as yet be definitely incriminated, cream is under grave suspicion. Since the beginning of the year it has not been permissible to add preservatives to cream and the suggestion has been made in many newspapers that there is some connexion between this prohibition and the present outbreak of infectious fever. A priori this is unlikely, for it has been shown that the maximum addition of boric acid heretofore customary—namely, 0·4 per cent.—has no effect on the growth or vitality of the paratyphoid bacillus, and that five times the quantity is needed to exert any restraint on the organism. It should be borne in mind, also, that in the ordinary course of events paratyphoid organisms in cream originate from the organisms in the raw milk from which the cream was derived. If it were true that they are commonly present in cream, but have hitherto been rendered innocuous by boric acid, then it would be difficult to explain why no milk-borne epidemic of paratyphoid has been recorded in recent years, for no preservatives have been tolerated in milk itself since 1912. This is not to say, of course, that cream, like other foods, may not be accidentally contaminated after separation. Five years ago a big epidemic owed its origin to ice-cream which had been cooled in filthy surroundings.

The paratyphoid outbreak has been confused in the public mind with a group of cases of food-poisoning among the London police force, leading to the death of a constable. But although they were coincident in time the two epidemics were fundamentally different in nature. The usual symptoms of infection with so-called food-poisoning bacilli are vomiting and diarrhœa, the excreta often being blood-stained. There is evidence of intense toxæmia, and the rapid onset, perhaps with prostration, is in marked contrast with the slow and mild development of illness due to paratyphoid-B. Acute enteritis following the ingestion of food used to be described as "ptomaine poisoning," when it was supposed that the symptoms were due to substances produced by the decomposition of proteins, but it is now recognised that the symptoms are due to the multiplication of organisms of the food-poisoning group within the intestine, and in severe cases within the blood stream. The food-poisoning bacilli occurring in preserved meats such as sausages, pies, and the like, may have come from an infected cow or pig, or from subsequent contamination of healthy meat. The meat or food may not present any unusual features either to the taste or smell, although there can often be isolated from it an organism identical with that obtained from the sick individual.

All these infecting agents, paratyphoid bacilli the food-poisoning organisms alike, however diffe may be their results clinically and epidemiologic are closely related and belong to the salmo group, which comprises a number of organ which cannot be distinguished from one ano under the microscope. Their biochemical chara are also similar and separation of member fermentation tests is not possible. They d in their serological relations, but even here the g relationship between certain types may be so as to demand complicated methods, such as ag tinin-absorption tests for their identification. the three types of paratyphoid bacilli, "A" does occur in this country, "C" is met with occasion while "B" infections are common, and in re years have assumed a greater relative import than typhoid fever. The food-poisoning b comprise: The *B. enteritidis* of Gaertner, which found in the recent police cases, and the *B. aertr* the commonest food-poisoner in this country which at least four types have been descri All these agree in the essential characteristics t (1) they multiply in food with great rapidity, e cially during warm weather; (2) during their gro in food they produce no physical changes vi to the naked eye; and (3) the toxins produced highly resistant to heat.

EXPERIMENTAL DENTAL CLINICS.

IT is generally agreed that in schools and indus enterprises the dental clinic has proved its worth, the Minister of Health has taken power, under Amending Act, to set up a number of experime clinics for dental treatment under the National He Insurance scheme. This experiment has a signific both for medical and dental practitioners, since t interests under the Acts are closely related.

The amount of dental additional benefit distrib has steadily increased during two valuation peri but it seems certain that its present partial and ditional application will extend over the perio the third valuation which is approaching. Notw standing the fact that nearly £2,000,000 per an is available for the purpose, the present schem far from covering the entire field. All insured per are not yet entitled to the benefit; those who eligible are called upon to pay a large proportio the cost of treatment, and none can claim it du those important years of adolescence from 16 t years of age. If we ignore these serious deficien it must be admitted that the scheme has been lar successful. A satisfactory system of dental ser has been evolved and maintained on a volun basis, and this is especially noteworthy becaus the original Act there was little provision for r lating the administration of additional bene and consequently the conditions of service—inclu the delicate matter of remuneration—had to negotiated by conference between representat of the dental profession and of approved soci in an atmosphere of imperfect mutual confide As it now stands the scheme is applicable to Engl Scotland, and Wales. It is managed by a De Benefit Joint Committee consisting of equal num of dentists and approved society representatives, v subsidiary committees for interpretation, investiga of disputes and for appeals; there is a Regional De Officer service, and there is even a disciplin tribunal consisting of a barrister and two de assessors. No panel in the medical sense is at pre

existence, but there has been no difficulty in curing the necessary service, the insured person being permitted to consult any dentist who is prepared to give the treatment on the agreed conditions.[1] A few approved societies have caused trouble by refusing to take part in the scheme, and their efforts to secure treatment for their members at fees lower than those of the agreed scale have had a disturbing effect. There have also been the inevitable clashes caused by lay officials who considered that control of the funds gave them the right to interfere with the professional discretion of the dentists. The latter, on their part, have occasionally shown an unfortunate sensitiveness as well as a somewhat irritating tendency to ignore agreed conditions. But, on the whole, the method of giving treatment through the agency of private dental practitioners seems to have justified itself, and this method is likely to remain the chief means for administering this important benefit. The demand for dental clinics was thus no warrant in any failure of the present system.

By no means new, the suggestion that clinics should be established was familiar to those who had to deal with the approved societies during the first valuation period, when it was put forward by certain officials with the frank intention of getting more effective control over the dentists they wished to employ. The idea was to place one or more dentists in operating rooms in proximity to the offices of the approved society, which would itself settle conditions of service, supervision, and remuneration; in short, it was desired to apply to dental insurance practice the methods of the pre-insurance "medical club" system. When later, on the constitution of the present Dental Benefit Joint Committee, the Minister of Health asked the Committee to inquire into "the possibility of the institution of clinics for dental treatment in particular areas and the desirability of encouraging steps to this end on the part of the dental profession," the earlier attitude towards the clinic question was largely abandoned, and stress was laid on the necessity for obtaining for insured persons a uniform standard of dental treatment in return for the payment of a uniform scale of fees. Attention was drawn to the advantages of large establishments, fitted with equipment and apparatus for special forms of diagnosis and treatment, and having facilities for team-work such as were not generally available in private surgeries; the clinic, it was expected, would also act as a propagandist centre for dental hygiene. The setting-up of such institutions is, however, only possible in populous areas, and preliminary inquiries on initial cost and running expenses do not encourage the idea that the present cost of treatment would be materially reduced. Nevertheless it is clear that clinics might play a useful though limited part in the future treatment of insured persons, and the assurances about their control, given by the Minister, and the actual embodiment in the Amending Act of the principle of free choice of dentist, have gone a long way towards reconciling the dental profession to an experiment of which it had been suspicious, as was hardly surprising. It must not be forgotten that the present position of the profession, of whose members only about one-half possess qualifications obtained after recognised courses of study and examination, necessarily results in a certain inequality of service available to those who get their dental treatment under the National Health Insurance scheme. The experimental clinics will test the possibility of providing a high standard of dental treatment in circumstances under which, otherwise, it may not be always available. If insured persons, of their own choice, attend them in sufficient numbers, and if the treatment given in the clinics is maintained at the level of excellence which is contemplated, their establishment will be justified from the standpoint of public health, and, in any case, the experiment, with all its results made freely available to interested parties, cannot fail to be useful.

[1] These are set out, together with full information on the working of the scheme, in a Dental Benefit Handbook compiled by the Dental Benefit Joint Committee and obtainable from H.M. Stationery Office at a nominal cost.

NON-PULMONARY TUBERCULOSIS.

SEVERAL important issues are raised in the papers in our present issue, by Mr. J. T. MORRISON on human and bovine types of tuberculosis in man, and by Dr. C. O. STALLYBRASS on the sources of infection. Both deal with non-pulmonary tuberculosis, a type of the disease which is all too often neglected in discussions on infectivity. Mr. MORRISON'S inquiry concerns the effects of inoculating guinea-pigs with material from tuberculous lesions, with a view to correlating clinical and bacteriological findings, and in almost one-third of the cases he found that this test was negative. For various reasons it is considered that failure to produce tuberculosis in the experimental animal was not due to the paucity of organisms, nor to a high state of immunity as reflected in the clinical course of the patient's illness; but rather to local conditions, such as the presence of fibrosis in the lesion from which the material was obtained. This view was supported by the long history of some of the cases, and seems by no means unreasonable, since it is well recognised that fibrotic and calcified foci are least likely to yield tubercle bacilli on animal inoculation. It would be a valuable aid to the elucidation of this point if material were inoculated from different portions of the lesions and at different times in the history of the same patient—i.e., in the early active stages and again in the later quiescent stages. An investigation into the human and bovine origin of these cases showed that failure to induce tuberculosis in the guinea-pig was as common with the one type of bacillus as with the other, so that the question of the relative toxicity of the two types of bacillus for the guinea-pig was apparently not considered to require investigation.

Mr. MORRISON raises a number of other questions on the regional distribution and clinical condition of the bovine and human groups. Tuberculous glands of the neck were found to be of bovine origin in 75 per cent. of cases, whilst the bovine bacillus was only responsible for 28 per cent. of the bone cases. These figures emphasise the need for a much more careful geographical survey of both bovine and human tuberculosis. Why, for instance, should Edinburgh have a high percentage of bovine lesions? Again, why should Jarrow, as shown by recent statistics, have a markedly higher total tuberculous incidence than Tyneside in general? Average figures for the country as a whole are of course of the utmost value, but there is some danger in assuming that they are necessarily typical of local conditions, and in so doing a remedial local factor may be overlooked. Statistics, moreover, do not remain of permanent value. Are we not in danger of making false deductions, for instance, from figures of positive findings of tubercle bacilli recorded in milk and butter in periods before the war? Every generation ought to make its own investigation afresh.

There is need, too, in the case of bovine tuberculosis for a regional survey of dairies and milk supplies, and we believe that such a survey might show that the bovine bacillus is not so widely distributed as was at one time believed. On the clinical side Mr. MORRISON'S inquiry shows that the history of onset of the disease was earlier in the bovine than in the human bacillus series. This again is important. It is likely that younger children, drinking more milk, are more prone to bovine infection than older children, but we have been led to believe of late that the human type of infection is also contracted during early years. Mr. MORRISON'S figures do not quite bear this out as far as non-pulmonary tuberculosis is concerned. A study of family history and an inquiry into possible portals of entry were not very successful as a guide to bovine versus human infection, but the results of treatment in the two types of case were remarkable. In all the bovine cases traced the patients were in good health, whereas more than 18 per cent. of the human cases had proved fatal within three years.

Dr. STALLYBRASS, also dealing with Liverpool cases, gives the results of inquiries into 4469 non-pulmonary cases of tuberculosis. From his figures it appears that tuberculosis of bones and joints is relatively common in patients giving no history of exposure to a human source of infection, whereas meningeal and abdominal tuberculosis—and to a less extent tuberculosis of peripheral glands—was in excess in those giving such a history. These deductions have to be somewhat modified for children, but, broadly speaking, Dr. STALLYBRASS thinks there is a direct contradiction between the figures as analysed for exposure or non-exposure to a possible source of human infection, and between the well-known results of bacteriological investigation. We are not so sure that exposure to human infection can be taken as a crucial test of invasion by the human bacillus. The tubercle bacillus is a slow starter, and the race is not always for the swift; the history of human infection may well be overlooked. The significance of certain details of personal history often escapes even the most skilled questioner, whilst the primary case in the household may remain dormant, from the physician's point of view, for many years. Conversely, bovine infection is rarely in evidence. On the whole, therefore, we are inclined to place most reliance on the bacteriological findings, but Mr. MORRISON and Dr. STALLYBRASS have raised many interesting questions, and are to be congratulated on exploring the field of non-pulmonary tuberculosis as against the pulmonary type of the disease. Far too little original work has been done of late years in this field, and it may well be that investigation of this kind will open up new views on the prevention of tuberculosis, particularly as regards contacts, disinfection, the milk problem, and the like. A large proportion of our national health budget is devoted to tuberculosis, and the elucidation of these questions may result in saving of money.

DONATIONS AND BEQUESTS.—The late Viscount Hambleden, among other bequests, left £5000 to King's College Hospital.—Mr. E. F. Goulburn, of Southport, left, subject to his wife's interest, £2000 to the Victoria University of Manchester to be applied for research purposes in connexion with megrim as affecting humanity, and £500 to Manchester and Salford Playing Fields Association.—Mr. Evan Lewis, Swansea, left £1000 to the Swansea General Hospital, to endow a bed.—Mr. W. R. Morris, head of the firm of Motor-car manufacturers at Oxford, and President of the Infirmary, has promised a gift of £38,000 for the extension of the Radcliffe Infirmary, Oxford. The gift will be used for the building of a new maternity home.—Mr. Tom Jackson, of Heaton, Bolton, left £1000 each to General Fund of the Victoria University, Manchester, the Bolton District Nursing Association, Dr. Barnardo's Homes, and the London Missionary Society.—Mr. Ernest George Wragg, of Ranmoor, Sheffield, left £1000 to the Jessop Hospital for Women to endow a bed in memory of his wife, £1000 to the Rotherham Hospital for the endowment of a bed in memory of his parents, and £500 to the Sheffield Children's Hospital for the endowment of the "William" cot.

Annotations.

"Ne quid nimis."

HEALTH HAZARDS IN INDUSTRY.

RECOGNITION is given in the United States to t social importance of the Registrar-General's Decenn Supplement dealing with Occupational Mortalit by the devotion of a whole Public Health Repo to a summary of its facts and deductions. We a thus afforded an opportunity of knowing how oth regard the data and their presentation. Ameri possesses no comparable material—nor, indeed, h any other country; and turns with avidity to o occupational mortality-rates as being exceptiona suggestive. The social distribution of mortalit portraying the influence of financial standing up disease, has little appeal to the United States, exce as introducing an element of uncertainty in occupational environment. Possibly a country prosperous as the United States finds even its lowe social class hardly at all hit by the dysgenic influen of penury. The association is noted of such digesti diseases as diabetes and diseases of the liver wi financial capacity for over-indulgence in diete indiscretions. Then attention is devoted to speci occupational comparisons in the search for clues hidden industrial hazards. Here the significance dust as a cause of tuberculosis, especially of sili dust, is stressed. The evidence adduced receiv synchronous support from research just published the Metropolitan Life Insurance Company of N York,[3] wherein the proportion of deaths fro tuberculosis for certain occupations with a sili dust hazard is shown to exceed the average for males: for metalliferous miners by 83 per cent., f pottery workers by 77 per cent., and for stone cutt by 44 per cent. A point is made that where th specific hazard exists there is a tendency for t phthisis mortality to rise steadily with age, and present a form of curve unique for this cause of deat The facts are carefully examined as to mortality d to all other respiratory diseases. Occupations wi high rates are placed in five groups: one is expos to dusts; a second to high temperatures—e. furnacemen; a third to inclement weather—e. dock labourers; a fourth contains rejects from oth trades—e.g., costermongers; and a fifth includes t alcoholics. In this connexion the incomparabili of death-rates in the two countries ascribed to chro bronchitis receives attention. In the United Stat certification of chronic bronchitis is discouraged, that in New York medical certificates stating chro bronchitis as a cause of death are sent back f revision. Hence bronchitis death-rates are usua about one-fourth those in England and Wales; wh cardiac death-rates are proportionately swollen, sin English bronchitis becomes American myocardit Direct occupational risks, however, affect a relativ small group of the working population, while t conditions of life implied by various occupatio exert subtle and pervasive influences on mortali in many indirect ways. The British data a recognised as providing evidence of the existence such influences.

INFLUENCE OF POSTURE ON RENAL FUNCTIO

THE relation of posture to albuminuria in susce tible subjects has long been recognised, and at o time came in for a good deal of investigation, b evidence on the effect of postural changes upon t renal function is still scanty. Exactly a quarter of

[3] Deaths from Tuberculosis in Dusty Trades. Statisti Bulletin, Metropolitan Life Insurance Co., vol. ix., No. June, 1928.

ury ago Linnoisier and Lemoine, using the hods then in vogue, adduced good evidence of ncrease in the activity of the kidney when the y was recumbent, but in spite of the development new methods of investigating the renal func- their results seem to have gone unconfirmed. Cordero and M. H. Friedman,[1] working in the siological Laboratories of the University of ago, have now reinvestigated the question, using ns of the phenolsulphonephthalein test of Rowntree Geraghty. They employed two normal subjects their experiments, which extended over seven ths, and their results show clearly a diminution xcretion of the dye in the upright and an increase he recumbent position. They were further able demonstrate corresponding alterations in the tion of water. A large body of evidence goes to v that the excretion of phenolsulphonephthalein s parallel to that of nitrogenous bodies in the e; Linnoisier and Lemoine demonstrated a ease in chloride excretion in the upright position an increase in the recumbent. In view of all these s the assumption seems fully justified that the mbent position favours, while the upright bits, renal activity. The why and wherefore of phenomenon remains as obscure as it was when noisier and Lemoine[2] originally produced the ory of torsion of the renal pedicle resulting from t posture. The American investigators suggest t increased urinary excretion in the recumbent tion may be due to increase of the capillary bed, ught about by vascular dilatation. Such a dila- on may depend not only on the recumbency, also on the general toning-down of nervous vity, such as precedes sleep. In support of this y adduce the fact that in one of their subjects, was of a nervous and excitable disposition, the uence of change of posture was less than in the other se nature was more phlegmatic.

E BROAD TAPEWORM IN NORTH AMERICA.

T was predicted over 30 years ago that *Diphyllo- rium latum* would become endemic in the upper insula of Michigan, seeing that its population tained immigrants who retained their Baltic habit ating uncooked fish, fresh, dried, smoked, or cured. prediction has proved correct, and T. Vergeer[3] has n investigating the steps by which this established ction is being maintained. Pike are almost ly implicated as the second intermediate host, t directly concerned in infecting man. They are he main migratory, passing from the Great Lakes the rivers to spawn, and in this way reaching tage Lake in the Michigan Peninsula, the spot re infection is greatest. One infected fish has n caught in Lake Superior, 20 miles from the mouth the Portage Canal, a distance which marks the it of the area investigated, so far as Lake Superior oncerned. The local crustacean intermediary has been determined. That the matter may come to e a more than local interest is suggested by the tement that 7,000,000 pounds of pike belonging to species which are locally infected were imported the United States from Canada in 1924, the last r for which figures are available, mostly fresh and rozen. It is concluded that it is necessary that se imported fish should be thoroughly examined the plerocercoids of *D. latum*. Knowledge of the ent, if any, to which they are infected would be uable, but if a complete food inspection is implied, s would probably be incompatible with the con- uance of the trade. Nor does there seem any tification for its institution in present circum- nces, seeing that the human infestation is definitely ociated with peculiar habits introduced by immi- nts of certain nationalities, that it is reported as limited to the area where these habits exist, and that within that area, it is, in the experience of those in local medical practice, less common than it was 20 years ago. It is significant that all the pike, some 30, examined from Lakes Erie and Douglas, were free from plerocercoids of this cestode.

RACIAL VARIATION IN THE SIZE OF RED BLOOD CELLS.

IT has generally been accepted that on the average the red cells of all the races of mankind are of the same size, but actual evidence of this has been wanting. Credit is therefore due to Dr. N. G. Winschnewsky[1] for adducing facts in support of this view. He has examined the red cells of 195 people of various races, all of whom had been domiciled for some months in Moscow, and he has found that the average size of the red cells in members of all the races tested falls within the accepted limits of normality. The extreme measurements of the diameter in the individuals examined were 6·64 μ and 7·83 μ, whilst for the different racial groups they were 7·14 μ and 7·34 μ. So far as it goes, this suggests that there is no appreciable difference between the dimensions of the red cells in individuals of different races living under the same conditions.

ACID DRINKS AND ENAMELLED VESSELS.

A FULL account of an interesting but rather alarming outbreak of sickness, which received some notice in the daily press, is given by Dr. J. A. Charles, assistant medical officer of health for Newcastle-upon-Tyne, in the current *Medical Officer*. Fortunately the investigation which followed the outbreak left no grounds of doubt as to the cause or as to the means of avoiding the possibility of similar occurrences.

A firm employing about 500 people were desirous, during the recent hot weather, of adding to the comfort of their employees by providing iced lemonade for their consumption. The "lemonade," like much of the drink provided under that name, was free from the characteristic acid of the lemon and its allies, citric acid; its place being taken by the usual substitute, tartaric acid. It is to the credit of the makers of the powder used that they called it "fruit crystals," and did not use any word suggesting that it was derived from lemons. The report of Dr. J. T. Dunn, who was called in to make an analytical investigation, showed that this was a perfectly harmless preparation, although a hasty test at the hospital, made when the first cases were brought in, led to the sufferers being treated for oxalic acid poisoning. An investigation of the circumstances attending the outbreak, which was rapid, both in the onset and the recovery of all the 70 odd persons attacked, showed that the crystals were dissolved in boiling water overnight in enamelled buckets obtained specially for the occasion, and extra sugar, over and above that in the crystals, added, with ice, in the morning. It may be noted, as having some small bearing on the case, that the amount of crystals used gave a solution of approximately double the strength of a liquid made strictly according to the makers' formula. Examination of the containing vessels, after the outbreak, showed that the enamel, where it had come in contact with the liquid, had lost its glazed appearance and that disintegrated enamel could easily be removed by rubbing with the finger. All the 12 buckets used were similarly affected, but a large metal bath in which a reserve supply was prepared and stored was not so attacked. Dr. Dunn found that the enamel of the pails contained antimony oxide equivalent to 5 per cent. of metallic antimony. This is by no means an unusual constituent of enamel glazes, and when vessels are intended for cooking the composition of the glaze

[1] Russian Jour. Trop. Med., 1928, vi., 141 (Abs.).

is usually so adjusted that the ordinary acid solutions likely to be used in culinary operations only remove inappreciable amounts of antimony in cases where that element is a constituent of the glaze. Antimony was also found in the "lemonade" taken from the pails. Owing to an oversight the liquid from the bath, which it was found was not enamelled with a fritted glaze, but had been painted with zinc white in linseed oil, was not examined, and it is not certain that any of the liquid in this was consumed, although at first there was an impression that those who drank only from this supply were not attacked by sickness. The lemonade from the pails contained 0·013 per cent. of metallic antimony. This, as Dr. Dunn points out, would represent in an ordinary 10 oz. tumbler gr. 0·57 of antimony, or gr. 1·52 of tartar emetic, whilst the emetic dose given in the British Pharmacopœia is gr. 0·5 to 1·0, so that drinking so little as one-third of a tumbler might be expected to cause sickness. No other heavy metals, such as arsenic or lead, were found in the drink, and the circumstances, including the symptoms observed, were all consistent with simple antimony poisoning.

It is unfortunate that so kind and thoughtful an action on the part of the firm concerned should have led to so much pain and inconvenience, but the tale serves to point some morals. Æsthetic and, perhaps, even common-sense considerations seem to suggest hesitation in adapting utensils designed for one purpose to another. The German makers of slop-pails, in glazing their interiors with a rather low-grade antimonial enamel, could hardly have foreseen that in the pioneer country of sanitary science they would be used as containers for beverages. Possibly, having regard to the adaptable character of the Briton, it might be desirable for such vessels, when sold, to bear a label: "not to be used for food or drink." Occurrences of this kind should receive the widest publicity; in fact, there should be some means whereby brief warnings could be compulsorily published in all newspapers. Further, some international standard for food containers might well be considered, as apart from acute visitations of the kind described, it is surely undesirable that the human body should become a receptacle for traces of antimony, tin, lead, arsenic, and other heavy metals. Last week 30 out of 60 of a party of boy scouts and girl guides were suddenly taken ill after having been regaled with cakes and lemonade, and were unable to return to camp until next morning. It is legitimate to wonder whether this outbreak was due to the same cause as the Newcastle one.

THROMBOSIS OF THE SPLENIC VEIN.

THE diagnosis of splenic anæmia is often made in cases which conform only vaguely to what many authorities regard as at best a vague disorder. From the mixed collection of cases grouped together under this name certain examples of thrombosis of the splenic vein have been separated off, principally by Wallgren, whose original paper has already been noticed in our columns.[1] At the discussion on chronic enlargements of the spleen in children, at the British Medical Association's meeting at Cardiff, Dr. Robert Hutchison referred to the occurrence of this condition in children, and described a case of his own; while in a recent article[2] G. Westkott makes a further contribution to the subject. The essential features of these cases of thrombosis of the splenic vein are the occurrence of severe hæmatemesis in association with enlargement of the spleen—which enlargement is less during and immediately after the hæmorrhage—and the absence of any evidence of cirrhosis of the liver or other cause for the symptoms. Westkott had under his care a girl of ten who was admitted with a profound anæmia, due, he believes, to severe infection with the intestinal parasite, *Trichocephalus dispar*. There was a history of hæmatemesis before admission, and a severe repeti of this followed a blood transfusion while she in hospital. Elaborate investigations were car out which excluded other causes of splenic enla ment; the blood count showed a severe second anæmia with very slow gradual improvement, un that following a serious hæmorrhage. In Westko paper the part played by the parasitic infectio discussed at some length, and the relation betw this and the thrombosis of the splenic vein wh was diagnosed is also considered. Operation not performed, so that confirmation of the diagn was not possible. It is believed that thrombosi these cases is probably the result of some infecti although the possibility of its connexion with severe loss of blood by the bowel due to the wo infection has also to be remembered. It may that the primary fault in these cases of splenic anæ is a thrombosed splenic vein, and the splenomeg which follows this may be responsible for the anæ and also for the character of the white cell cou with leucopenia, so frequently found. Westk does not come to any definite conclusions except confirm the idea advanced by Wallgren, that spl vein thrombosis is a clinical entity. The case describes opens up further possibilities as to ætiology of the condition.

THERAPEUTIC MIRACLES AT HEREFORD.

IN his History of Hereford Cathedral the late Ca Bannister states that, as a general rule, the mira recorded in the "Lives" of mediaeval saints vaguely described and poorly attested. But of th wrought at the tomb of St. Thomas de Cantilup seems that there exists an official account, drawn by six lawyers after investigations made by pa commissioners. Two of these—Ralph Baldo Bishop of London, and the Bishop of Mende—ca to Hereford at the end of August, 1307, and stayed Nov. 16th, *omni die ex industria intuentes ecclesi* Pope John XXII., in the Bull of canonisati declares that 17 miracles were thoroughly investiga and found to be *fidelibus probata testimoniis*. A la proportion of these 17 miracles were cures of cases palsy, but three deal with cases of blindness, Bannister says that the evidence for them is proba better attested than the evidence for marvellous cu at any other shrine. The fifteenth of the se concerns Agnes de la Brok, of the parish of St. Martin Hereford, cured of blindness on the Friday after t octave of Easter, 1287. One witness affirmed t Agnes was well-to-do, so that there was no appar reason for her wishing to make money out of infirmity. Several witnesses deposed that she h not in her blinded eyes, *vulnera, apostema, tumor maculam, vel aegritudionem vel aliquam apparen laesionem*. This seems to have been a case of hysteri blindness. Last in the series of cures come two sm boys, brothers, aged 4 and 5 years respective healed of their blindness, also in 1287. *Mali humo effluebant ex oculis, et aliquando claudebantur palpeb dictorum oculorum: tunc ipsi oculi inflabantur, putredine congregata in eis denuo palpebrae aperiebant* Obviously these were cases of simple catarr ophthalmia. Presumably Agnes and the childr had died or passed out of ken during the 20 ye intervening between their miraculous cures and t official inquiry, or their first-hand testimony wo have been obtained.

Judged by modern standards one feels that t six lawyers who investigated these cures must ha been very easily satisfied, but the inquiry was h upon the findings of papal commissioners, and wh St. Thomas de Cantilupe, recently dead, was at t crest of his fame as a miracle worker. For this sai one of the most celebrated of the Bishops of Herefo died on August 25th, 1282, at Civita Vecchia. He reputed to have been of a saintly disposition, and w certainly steadfast and unyielding in upholding t rights of the See. There is, so far as we are awa

evidence to show that during his life he had any tive connexion with the healing art, but numerous res were reputed to have been wrought at his rine after and before his canonisation. He was cted bishop in 1275, succeeding Peter of Savoy quablanca). He had served as Chancellor of the iversity of Oxford, and as Chancellor of England, der Simon de Montfort. He was stern in his sistance of encroachments on his liberties, upholding s rights in Malvern Chase against Gilbert de Clare, e Red Earl of Gloucester; disputing with Llewellyn Wales and with Lord Clifford, the latter for cattle ting. Lord Clifford performed penance and under- nt a birching in the cathedral. The bishop's most ere wrangle was with his metropolitan, John de ckham, over a question of testamentary jurisdiction. communicated by the Archbishop, he went to Rome d secured from Pope Martin IV. a decree in his our. On his way back he died, as stated above, d was buried in Florence. His bones were separated m the flesh by boiling and brought to Hereford and ced in the cathedral. His old enemy, the Red Earl, ended the ceremony, and at his approach, the iscopal bones were seen to bleed! Forty years er he was canonised. An enormous number of racles resulted. More than 66 dead persons were tored to life. His shrine even acquired a sort of terinary reputation, and Edward I. sent sick falcons be cured at his tomb. The six lawyers, it will be n, were asked to dismiss from their minds an extra- linary amount of influential matter before giving ir verdict.

HEALTH TALKS.

IN the Public Health Section of the British Medical sociation's Cardiff meeting Dr. W. W. Jameson alt with the important and difficult subject of health ucation, particularly welcoming the use of broad- sting as a means to that end. He commended the ggestion recently made in *Public Health* (May, 1928) at the present method of broadcasting once a nth a "health talk" lasting 15 minutes is unlikely serve the cause of education so well as more frequent ur-minute broadcasts on matters of special health erest at the particular moment. He also spoke of agreement which had been reached with the neral Medical Council in regard to the publication health articles in the daily press, in which connexion eading newspaper reported him as follows:—

"It was now accepted that such articles should be sub- ted to the Chief Medical Officer of the Ministry of Health his approval and that approval would be forthcoming vided the article was (*a*) for the public benefit, and free from the taint of personal professional advertise- nt. Articles approved by the chief Medical Officer might signed by the author and might then be distributed ough one of the press associations."

These statements may easily be interpreted as an cial decision on the vexed question of signed ntributions by medical men to the public press, t the facts do not justify such a reading. For some ne past the British Broadcasting Corporation has mitted to Sir George Newman, the Chief Medical icer of the Ministry of Health, such talks on health they were proposing to broadcast, with a view to uring himself that the matter to be broadcasted s for the public benefit and free from the taint of sonal professional advertising. It seems that the ntral Council for Health Education, a recent develop- nt of the Society of Medical Officers of Health, posed to distribute through the press associations egular series of articles dealing with health subjects, l asked Sir George Newman for his advice whether publication of such signed articles would be regarded unobjectionable by the General Medical Council if authors were (*a*) senior whole-time medical cers of the public health service who in the ordinary rse were not likely to apply for promotion to other pointments; or (*b*) retired medical officers no ger seeking professional employment. The Registrar of the General Medical Council, when consulted, thought it desirable that the same principles should apply to this special series of signed articles as to the special wireless talks, and Sir George Newman expressed his willingness to exercise the same censorship over the publication of articles of this kind as he has done in regard to broadcasting. This is, we understand, the position which has been reached at the moment.

MENTAL DISORDERS IN SCOTLAND.

THE record of last year's care of the mentally afflicted and deficient of Scotland[1] contains no mention of novel departures or striking events, but proves that the foundations of lunacy administration are being strengthened and that healthy ideas are gaining ground. The total number of persons under the Scottish Board of Control at the beginning of this year was 18,702, an increase over last year of 122; this increase is all in the pauper class of patients, the number of private patients having slightly decreased. The number of admissions to asylums was 3168, which is 133 more than in the previous year, but 458 less than the average for the previous quinquennium; 703 voluntary patients were admitted, and 815 were resident on Jan. 1st last. This figure shows a remarkable increase, the average for the ten years 1918–27 being only 409. The average recovery-rate on admissions in all institutions, with the exception of lunatic wards of poor-houses, was about 34 per cent (no general rate is given in the report), and the average death-rate was 8·5 per cent. Most of the deaths were due to diseases of the circulation and brain, and there were only seven suicides. The number of mental defectives on the register was 2915, the admissions being slightly less than in the previous year. In discussing the life of defectives in private dwellings one of the commissioners points out once more that strangers look after them better than their own relatives. This fact is well known to all connected with the care of the mentally afflicted, but its explanation is not at first sight obvious. A patient living with strangers may be removed, and guardians will make strenuous efforts to avoid the stigma which they consider this will entail. Parents, from whom the patient cannot easily be removed, are apt to regard themselves as infallible. Many of these parents, moreover, possess a low intelligence and a rudimentary idea of cleanliness. When aliment is stopped because the family's circumstances have improved or the defective has obtained employment, patients and guardians alike are generally anxious to be free from official supervision. These, however, are the cases in which supervision is most necessary, as the labour of defectives is liable to be exploited.

The Board refer to the success of the observation wards which several parish councils have established and which are conducted on hospital lines. Of 1240 patients who passed through those at Stobhill and Duke-street in one year, 788 returned to their homes without the necessity for certification. The Board are anxious to extend the scheme. As they remark, the Royal Commission of 1927 recommended that the functions of the Board of Control and the General Board should be extended to include all matters relating to mental health. The annual lunacy grant, which amounts to £115,000, is given to improve the care of the mentally afflicted, and this object, in the opinion both of the Scottish General Board and of all who are concerned with the problem, would be better accomplished if, instead of remaining as it is—a grant in aid of certified lunatics—it were given to the Board to use at their discretion for the good of all mentally affected persons other than defectives. It could then be applied to the source of the evil instead of to its full flood, and would be many times more effective.

CIVILIANS AND BOMBARDMENT FROM THE AIR.

THIS week's manœuvres over London and the home counties seem to show that complete protection of a large city from aerial attack is at present impossible. It is a military axiom that means of defence never lag far behind means of attack, but for the moment, given equal forces, there is evidently no way of preventing a capital city from suffering severely by bomb-fire. The contents of the bombs to be used in true warfare are a matter of conjecture, but there is little reason to doubt that poison gas would be freely employed, and it may be of interest to recall the steps that are recommended to neutralise its effects. These were set out recently before the Academy of Medicine in Paris by Inspector-General Sieur,[1] who summarised a scheme agreed upon by the International Red Cross for the protection of civilians. This scheme was drafted in 1925 by a committee of experts —chemists, engineers, doctors, administrators, and workmen. Recognising that it is impracticable to supply everyone with individual protective apparatus of the best kind, it divides the community into two classes, active and passive. Active members—police, firemen, first-aid workers, and the like—receive the best possible equipment; passive members are given cheaper and more simple appliances which may safeguard them under ordinary conditions, but they must chiefly rely on being protected collectively. As a gas attack is likely to include attack by explosives, small bomb-proof shelters should be made to accommodate not more than a dozen persons. Any room, it is stated, can be rendered proof against non-lingering gases by hanging its openings with fabrics steeped in appropriate solutions or specially prepared, but it is better to use tightly fitting panels and maintain, by means of artificial ventilation, a pressure slightly above that of the surrounding atmosphere. The air should be taken from as great a height as possible and filtered mechanically and chemically; in shelters to be occupied by children or the sick and aged there should be a supply of oxygen. Shelters are best established in cellars, and there should be a stout layer of impervious flag-stones or concrete flooring over each, and where possible on each floor of the building. Besides these refuges there should be first-aid posts, special hospitals, and means for the transport of injured persons. Lingering gas imposes a serious problem, as it is highly poisonous and may contain pathogenic organisms. All places contaminated should be immediately cleared of their occupants and disinfected, and the occupants should be taken for bathing and disinfection to special stations, and should be excluded from ordinary shelters. Food and drinking-water should be protected, and municipal water-supplies should be covered with an impermeable mineral flooring, whilst gas and electrical conduits should be guarded against explosives. These provisions, said Dr. Sieur, should all be made in peace-time by committees of military and civil authorities, with representative citizens, for each district. The first-aid corps—in this country presumably composed of ambulance workers and trained volunteers—should be distinct from the disinfecting corps, which should be supplied by the fire brigade where there is one, and recruited from volunteers and local sporting organisations where there is none. He states that the British Red Cross is already training its personnel on these lines, but obviously the population here is wholly unprepared for a modern air-raid, whilst neither individuals nor municipalities are likely to plan their undertakings with aerial warfare in view.

GIFT TO RADCLIFFE INFIRMARY.—Mr. W. R. Morris, the motor manufacturer, has given £38,000 for the building of a new maternity home at this hospital. He is the President of the Governing Body.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT CARDIFF.

(*Continued from p. 302.*)

SECTION OF MENTAL DISEASES AND NEUROLOGY.

AUTO-TOXÆMIA AS A FACTOR IN THE CAUSATION O PSYCHOSES.

Prof. W. WEYGANDT (Hamburg), in opening th discussion, pointed out that with the advance in th pathological anatomy of the central nervous systen it had become more apparent that mental derang ments were cerebral diseases, and that a morbi influence on the brain was the cause of mental di orders. The biological investigation of ment derangements was all the more important as th morbid anatomy of the brain had not fulfilled expe tations, nor had experimental psychology or psych analysis led to very definite results. Prof. Weygan then considered in detail the forms of retarded develo ment in relation to metabolism of the endocri glands. Disturbances of the thyroid gland in chil hood led to retarded growth and delayed or abse sexual development as well as to mental retardatio Treatment with thyroid relieved such symptom excellent results were also obtained in myxœdem In Graves's disease removal of a portion of t gland by operation was an important procedu but thymus and ovarian preparations had also be employed. The speaker referred to the fact th giantism and acromegaly were sometimes associat with idiocy, in addition to Fröhlich's syndrome. such cases a primary disorder of the cerebral cort was presumably present.

Prof. Weygandt considered that the thymus h also a relation to mental evolution. Klose h removed the thymus in young dogs and observ that the animals developed obesity and ceased grow, became stupid, tried to eat wood and ston and eventually died. H. Vogt had described thym idiocy in a dwarf, aged 17, with flabby muscles, frag bones, general tremors, and retarded general develo ment. As regards the suprarenal glands, Addiso disease was sometimes associated with headac depression, fatigue, insomnia, and deficient memo Strictly speaking, there was no such condition as uniglandular disorder, for after the loss of one end crine gland, changes in the other glands would occ In mongolism the physical signs were those retarded development, and might be associated w signs of thyroid or pituitary deficiency. Kafka h shown that the serum in most cases gave a weak b distinct "decomposition" reaction (Abderhalden) the pituitary gland. Also, the white blood cells w increased, while the viscosity of the blood plasma w decreased. Prof. Weygandt considered that mo golism was not syphilitic in origin. One of the m important problems in psychiatry was to determ the pathogenesis of dementia præcox (schizophreni Pathological changes had been found in certa cerebral cells, especially those of the third stratu of the cortex. The fifth and sixth strata might a show atrophic changes. The contention of M that degeneration of the spermogenic cells a Leydid cells was the basis of the disorder was n generally admitted. Prof. Weygandt considered th endocrine degeneration, as shown by Abderhalc reactions, was most important, although many h these reactions in doubt. If a disorder of metabolis and especially of the endocrine organs, affected brain rendered somewhat abnormal by heredi conditions were favourable to the development schizophrenia. Entirely different, in Prof. Weygand opinion, were the basic conditions of manic-depress psychosis (cyclothymia). The inherited factor in t disease was paramount and could be traced in per cent. of cases. There appeared to be no questio

anatomical basis, and he considered that we could ribute little or no importance to the factor of toxæmia. There was present an instability of ective mind resulting from heredity and possibly nected with vasomotor variations.

Autotoxæmia was of considerable importance in e or idiopathic epilepsy as distinct from symptotic epilepsy. In many cases it was possible to monstrate anatomical changes. For instance, iner had described gliosis of the cerebral cortex, aslin alterations in the cornu ammonis, Speilmeyer tomeningitis. Endocrine influences might also y a part, the suprarenal, thymus, corpus luteum, l possibly the pineal gland, all tending to rease the instability of the cerebrum and to prepose to convulsions, while the parathyroids, gonads, uitary, and possibly the pancreas, decreased this idency. Hepatic influence in mental disorders nained uncertain. Kirschbaum had described eneration in the corpus striatum and pallidum the cerebral cortex in association with acute yellow ophy of the liver. Prof. Weygandt attached no at importance to bodily fatigue and hunger, in the duction of mental disease, but insomnia might have efinite influence.

In summarising, Prof. Weygandt stated that in ny cases of mental disorder considerably biological and biochemical changes occurred which could explained by autotoxæmia. The facts discussed l also been applied to treatment. Preparations of roid gland were successful in the treatment of xœdema and cretinism, while results in pituitary orders had been obtained by X ray applications l glandular feeding. Malarial treatment, successful many cases of general paralysis, had not yet been nd to influence dementia præcox nor epilepsy. th diagnosis and treatment demanded that estigation of the autotoxæmic influences in chroses should be regarded as one of the most portant researches in psychiatry.

Dr. F. A. Pickworth (Birmingham) brought forrd some work which was being done in Birmingham connexion with the joint Board of Research for ntal Diseases and the Birmingham Mental Hosals. The question of focal and intestinal sepsis l been studied very carefully. They had found dence of infection with organisms of the paraphoid and food-poisoning groups which was conered to have a causal relation to focal sepsis riation in agglutinin response and metabolic turbance. A special study had been made of the ation of sinusitis of the sphenoid to pituitary turbance, and pituitary dysfunction might explain ne of the symptoms of endocrine deficiency. Dr. kworth showed slides illustrating: (1) the sphenoid us containing pus, and demonstrating that the uitary gland had very little protection from the anisms and toxins which invaded the damaged thelium; (2) a perforation into the pituitary sa from a sphenoidal sinusitis. Other slides illusted actual infection of the pituitary fossa, and one wed a number of organisms in a large mass of loid in the pituitary capsule, suggesting that normally large masses of colloid in the pituitary l relation to septic involvement of the gland. en septic involvement of the pituitary, it was sonable to suppose that septic products, or at st a perverted pituitary secretion, was able to reach in tissue.

Dr. E. Mapother (London) thought all were equally eed that every mental process was only the jective aspect of a bodily one which left traces l originated habits and reactions. As regards ss endocrine abnormalities and mental disorder, Mapother thought that the evidence suggested t in most cases, with the possible exception of thyroid, the association was rather one of frequent urrences than of causal dependence. He had own dystrophia-adiposo-genitalis coexist with fect mental normality; similarly, giantism was only occasionally associated with mental defect. Concerning genital glands, he thought that, if we interested ourselves in evidence of functional disturbances rather than gross anatomical changes, the history given by many patients was significant. Sexual disturbances and the psychological reactions arising therefrom, appeared of more psychiatric importance than all the rest of the endocrine disorders. Such conditions as erotism and nymphomania on the one hand, impotence and frigidity on the other, were extremely common, and the reactions arising from these conditions were most important.

Dr. I. S. Wile (New York) considered that the terms toxæmia and psychoses were employed in too broad a sense. They could not disregard heredity, infections, &c. Endocrine disorders and psychoses might be due to a common underlying cause, such as syphilis; concomitant as in association with cerebral tumour and diabetes; or in causal relation as mental enfeeblement and athyroidism. It was necessary to show causal relationship rather than coexistence of symptoms. At present all phases of study were essential to secure material facts from which later generalisations might be made. For many years it would be advisable to accumulate data regarding heredity, infection, trauma, and metabolism. Equally important were the appreciation of the psychological and psychogenetic factors entering into psychoses in relation to toxæmia.

Dr. Mary Barkas (London) advanced the view that the association of physical disorders with mental disease might be explained otherwise than as direct causes, and that the psychiatrist might promote the development of psychiatry far more by concentrating on the study of the mental processes of patients than by a flight into the laboratory. Dr. Barkas thought that plausible explanations of the association of bodily manifestations with psychosis could be offered. She believed that autotoxæmia and similar disorders might be related to mental disorder in the following ways: (1) as a precipitating factor; (2) as a source of mental stress; (3) as joint effect of some primary cause; (4) as chance concomitant; (5) as result of the mental and emotional or psychomotor disorder. It must also be remembered that while they were dealing with those cases of disordered bodily function which were insane, there remained in the general population far larger numbers suffering from similar disorders, but free from mental illness; the speaker held that it was for them as psychiatrists to investigate what were the other factors, lying perhaps in the inherited constitution and temperament, in the individual development of personality, or in the foregoing emotional situation of their patients, which had determined the mental breakdown. The physical disorder might have been the last straw, making a pre-existing burden of a stress intolerable, and its removal might make readjustment possible. Various endocrine defects might produce dwarfism, but many dwarfs were of quite normal mentality, notably achondroplasics, and some forms of pituitary infantilism. Where they were mentally abnormal, might we not equally well suppose that their mental symptoms were a reaction to their bodily abnormality, which produced a sense of inferiority or an attempt to over-compensate for this, cunning or suspiciousness, and an attitude of defence to make up for lack of physical strength, and a whole series of other mental reactions. Until we had studied these mental phenomena in sane and insane alike who laboured under endocrine disorder, we were not in a position to assert that mental symptoms, when found, were directly produced by the metabolic dysfunction.

Dr. R. D. Gillespie (London) said that the conception of autotoxæmia in this country had been restricted largely to conditions of supposed intestinal absorption. The bacteriology of the colon in persons mentally normal was in too vague a condition to make it safe to draw definite conclusions from a bacterial examination of the fæces in the psychoses. Similarly, regarding Dr. Pickworth's observations, it was

dangerous for him to argue from his interesting findings to the psychoses in general. Regarding intestinal toxæmia, clinical experience with Hirschsprung's disease showed that mental symptoms were usually absent in spite of the extreme intestinal stasis. Ulcerative colitis, in which toxic absorption certainly occurred, was not, as a rule, accompanied by mental changes, whereas mental symptoms often accompanied so-called mucous colitis, in which absorption was probably absent.

Dr. HELEN BOYLE (Brighton) looked at patients from the clinical side: What was the matter with them? What would cure them? How long would it be? It was encouraging that Prof. Weygandt mentioned recovery in dementia præcox, and clinicians would agree with him that some such cases appeared to recover. His paper suggested a hope that some test might serve to differentiate these cases from others. It was not satisfactory to assume merely that should recovery occur, the diagnosis was wrong. With regard to manic-depressive states, Dr. Boyle said that many patients seemed to show an association with Graves's disease. This was more obvious in the early stages, but even in confirmed cases the description of excitement, tendency pyrexia, rapid pulse, sweating, and other symptoms suggested hyperthyroidism. There was not infrequently an enlarged thyroid. When this phase subsided, the picture often suggested hypothyroidism—as though the thyroid was fatigued and could do no more. There was depression, weight increased, the patients were slow and weary, with lack of interest, and in exactly the reverse of their previous states.

Dr. E. GOODALL (Cardiff), the President, remarked that many acute and recent cases of mental disorder improved in large measure with a preliminary enema or colonic lavages. In Cardiff they had published from the Mental Hospital laboratory work upon the distribution of the various nitrogen constituents of plasma, cerebro-spinal fluid, and urine in some 40 (mostly recent) cases of mental disorder, and the results appeared to point to anomalies of protein metabolism. With regard to blood chemistry, the methods for the estimation of blood substances were at present far from adequate. Reliable methods for the estimation of glucose alone had still to be elaborated; also with cholesterol, the statements published regarding a diminution or excess of blood cholesterol in epilepsy and at the menstrual period were unreliable. Some 15 years had passed since Fauser published his results with the Abderhalden reaction in cases of dementia præcox and other mental disorders. His results at that time were mainly confirmed, and there seemed to be evidence that a positive reaction was obtained by Abderhalden's method with cerebral cortex and gonadal tissue in dementia præcox. Of late years one had heard and read little or nothing of the Abderhalden reaction in psychiatry, so that it was of interest to hear Prof. Weygandt's opinion that this method gives a positive result as regards blood and cerebro-spinal fluid in dementia præcox, not only of cerebral cortex and gonads, but often with thyroid and pituitary. If this were so, a means of diagnosis between true dementia præcox, and other mental conditions resembling it, should be established. The difficulty of carrying out the test no doubt accounted for its general non-employment.

CEREBRAL STATES CONSEQUENT UPON HEAD INJURIES.

A discussion on the differential diagnosis and treatment of these states was opened by Dr. C. P. SYMONDS (London). Apart from the immediate surgical risks of compound fracture, rupture of a meningeal artery, and subdural hæmatoma, the severity of head injury varied according to the nature and amount of damage sustained by the brain at the time of injury. When such injury did not prove fatal, there would result cerebral symptoms the differential diagnosis and treatment of which the speaker proposed to discuss. Concussion might be defined as a condition of subtotal cessat of cerebral function following immediately upon injury, with subsequent complete recovery wit 24 hours, at the end of which, in an uncomplica case of concussion, recovery should be compl The symptoms were probably due to tempor vascular embarrassment. Distinct from concussi though often associated with it, was the condit of cerebral contusion. The symptoms of cere contusion depended upon two factors: (1) the eff upon intracranial pressure, and (2) the site of lesion. The focal signs of the latter were those cerebral disease generally. The effect upon int cranial pressure depended upon the amount hæmorrhage and exudation. For the purposes clinical description, Dr. Symonds distinguis between a major and a minor degree of contusi The major form was almost always associated w concussion; after a few hours the patient parti regained consciousness, but instead of progress towards normal, he remained stuporose, restless irritable and might be noisy, hallucinated and e violent. This condition might persist for s days or weeks, the tendency being towards grad improvement. Lumbar puncture and the applicat of a manometer might show the presence of increa intracranial pressure; the cerebro-spinal fluid mi be blood-stained, indicating capillary hæmorrh In minor contusion, the injury might or might cause concussion. It was possible for a glanc blow to contuse the brain, without loss of consci ness at the time of injury. Symptoms might fol directly upon the injury, but more usually develo after a latent period varying from hours to we The three symptoms most constantly present w headache, giddiness, and mental impairment. characteristic feature of the headache was its rela to alterations of posture. The mental sympt consisted of defective memory, inability to con trate, decreased emotional control, and me fatigue. Apart from focal physical signs which v rarely encountered, there were other conditi such as epilepsy and permanent mental cha which must be related to local damage. Mi degrees of mental impairment—e.g., memory defect were frequent, but permanent mental deteriora necessitating institutional treatment appeared r Epileptic atacks might occur even in the e stages of a major contusion and were probably to subarachnoid hæmorrhage; attacks develo after a latent interval of months or years wer more serious significance. Cerebral abscess follov a compound fracture, and chronic subdural hæmato although both rare, were two sequelæ of head in which the neurologist was likely to encounter. subdural hæmatoma the patient began to comp of headaches usually several weeks after the orig blow. Other symptoms of intracranial pres gradually appeared, with stupor and finally co Owing to the long latent period and possibly tri nature of the original injury the diagnosis sometimes mistaken. The cerebro-spinal fluid m be found to contain altered blood-pigment flakes of fibrin. Finally, there was a consider number of cases in which the disability follo head injury was wholly or partly of a neurotic na and usually based upon the problem of compensat

As regards diagnosis, Dr. Symonds said that du the first 24 hours it was impossible to make a c prehensive diagnosis owing to the state of concus masking what lay behind. If, however, after pa or complete recovery of consciousness the pat sank again into true coma, or paralytic s developed, arterial hæmorrhage was almost certa present. The absence of concussion did not exc the possibility of symptoms of contusion or subc hæmatoma developing at a later stage. Stupor irritability after the first 24 hours indicated m cerebral contusion. A patient might appare recover and yet develop symptoms of minor contu after several weeks. Since the symptoms of m contusion were as a rule unassociated with phy

gns, it was often difficult to distinguish them from ıose of an anxiety state. Of particular importance the differential diagnosis was the character of the eadaches and their relation to posture. In neurosis ıe headache was continuous rather than inter-ittent, had little or no relation to posture, and was ggravated by mental stress. In true contusion the eadache might be associated with giddiness, also lated to posture, retardation of mental processes ıd defective memory for recent events were valuable gns of cerebral damage. It was important to member that the brain might be severely damaged ithout fracture of the skull or objective physical gns, and that, conversely, fracture of the skull as not in itself proof of cerebral injury. The gns of subdural hæmatoma were often those of erebral tumour—papilloedema, hemiplegia, &c.—and ıe cerebro-spinal fluid might exhibit xanthochromia ıd fibrin flakes.

As regards treatment in major contusion, relief intracranial pressure might be obtained, either y lumbar puncture repeated at two-day intervals, necessary, or by intravenous injection of 50–100 c.cm. 15 per cent. hypertonic saline. The effect of this tter was to cause shrinkage of the brain by absorp-on into the blood stream of extravascular fluid ntents. The effect was temporary only and the ocedure might have to be repeated at intervals two days. An alternative method was to give saturated solution of magnesium sulphate (3 oz. in oz. of water) by the rectum; to be effective, this lution should be retained for half an hour. In a ries of 80 patients with symptoms of cerebral ntusion Dr. Symonds found that 18, or 22·5 per cent., ated that they had made a complete recovery. ı cases of major contusion the chances of the patient ing able to return to full work were less than 1 in 3, ıd there was the same chance of total incapacity. ı cases of lesser injury, there was an even chance the patient being able to return to full work, and very small risk of total incapacity.

Dr. C. WORSTER-DROUGHT (London) entirely reed with Dr. Symonds in his statement that the ain might be very seriously damaged without acture of the skull, or indeed, evidence of bone jury. In assessing the effects and possible conse-ıences of head injury, far too much stress was laid on the radiographic appearance of the skull, and negative, the cerebral injury was often assumed—t only in legal, but also medical circles—to have en slight.

In his experience, the after-effects of what has en described as major contusion were more often vere than not—and personally he would not have aced the rate of complete recovery in these cases high as 22·5 per cent. Cerebral contusion might ıd to localised adhesions between the dura, achnoid, and cerebral cortex and so give rise to ilepsy—and all without X ray evidence of bone ımage. This was strikingly illustrated in one case at came under his observation—a case also teworthy on account of the excellent result of rgical treatment. A man, aged 28, fell, striking s head on the junction of two tram lines. Three ars after the accident his first epileptic fit occurred, ere being no previous history of epilepsy. Examina-ın showed a scar in the supra-occipital region, ıt no other physical signs.

The region of the scar was trephined, and when e piece of bone was removed, the dura on incision ıs found to be adherent to the underlying cortex. r. Worster-Drought had had this patient under servation since the time of operation—six and a lf years—and no further epileptic attack had curred; the patient returned to work and was cellent health. Equally successful was another se of traumatic epilepsy, due to a lesion that might described as unusual form of subdural hæmatoma the posterior parietal region. An interesting int was how long after a head injury could epilepsy pear? In his experience, it had been common r epilepsy to appear three or four years after the accident, and he had met with cases in which the first epileptic attack had occurred 10 and even 12 years after the head injury. As regards treatment of traumatic epilepsy, the conclusion was that in the presence of definite evidence of the site of injury, such as a scar, &c.—even if radiographic appearances were negative and in the absence of other localising physical signs—operation was worth while. He would not advise operation in the absence of physical signs or of some evidence indicating the site of injury. The mental sequelæ of cerebral contusion were often peculiar. One somewhat unusual effect was complete and apparently permanent inability to perform mental work, of which Dr. Worster-Drought gave examples.

Dr. Worster-Drought considered that head injuries in the left frontal region were the most serious as regards prognosis in respect of mental changes. A condition of dementia might result from damage in this situation. He had seen such cases, and one example he described. In view of the fact that W. E. Dandy, in America, had recently excised the right cerebral hemisphere in man without, it was reported, the patient showing evidence of mental change, such injuries to the left frontal region were of interest in its possible localisation of the main seat of intellectual activity. As regards treatment, Dr. Worster-Drought was not convinced of the practical value of intravenous injection of hypertonic saline. The relief of symptoms afforded was somewhat uncertain and transient. He mentioned experiments supporting this contention. He was inclined to regard lumbar puncture, repeated if necessary, as the best means of relieving intracranial pressure. The continued administration of saline substances either by the mouth or rectum might, however, also be of value. For chronic and persistent headache following head injury, when repeated lumbar puncture failed to give permanent relief, Dr. Worster-Drought was in favour of sub-temporal decompression. He had seen several cases in which this operation had given excellent results.

Dr. WILE remarked that in children cerebral contusion might lead to changes in personality accompanied by delinquency and epileptic equivalents, resembling some of the sequelæ of encephalitis lethargica. It was necessary carefully to distinguish the headache, giddiness, and various mental disabilities following minor contusion from psychoneurotic symptoms. It was important to apply psychological tests in determining defects of memory, whether visual or auditory, for recent or remote events. The relation of cerebral injuries to later educational disabilities could only be determined by more thorough psychological investigation. Traumatic neuroses might be exaggerated in frequency, but it is wise to be certain that minor mental symptoms were not functional before suggesting that they were the residua of organic disease or cerebral injury. He agreed that emphasis was necessary upon the statement that fracture of the skull was not proof of cerebral damage, and that, conversely, damage of the brain might exist without a fracture of the skull. In order to interpret the actual state of a patient following cerebral injury, it was necessary to know if he returned to his earlier occupation, or was subject to further re-education, or was obliged to change by reason of changing industrial conditions.

Dr. GILLESPIE said that the classical psychotic syndromes had no definite ætiological relationship to trauma, and certifiable insanity rarely occurred as the result of head injury. In some cases that had been recorded other factors had been prominent, such as alcoholism, and heredity. Several forms of late after-effects could be distinguished, including traumatic mental enfeeblement and behaviour disorders. The chief difficulty arose in the diagnosis of these defect-states from those of psychoneurosis; nevertheless definite criteria existed, such as slowing of thought, attention defect, and mood disorders. Also the

patient should invariably be considered as a whole, especially his previous personality.

Mr. WILFRED TROTTER (London) said that until recent years a whole train of symptoms following head injury had been regarded as vaguely due to hysteria, malingering, &c., but that such symptoms had been brought under scientific observation and were no longer so vague and indefinable. It was possible to distinguish as precisely as anything in medicine a form of amnesia that was characteristic of true concussion. This was retrograde amnesia—a loss of memory for events preceding the accident, the patient having no recollection for anything that occurred during the 15 to 20 minutes that preceded his head injury. A further point of importance in diagnosis was that in the headache following minor contusion the patient when free from such headache felt perfectly well; this was not the case with the psychoneurotic.

For intractable headache following minor contusion a decompression operation was indicated. In major contusion, Mr. Trotter doubted if one was justified in leaving the brain in a seriously congested condition over a long period. He advocated the special operation of making a small opening in the skull to interrupt the vicious circle of compression.

Dr. D. MCALPINE (London) confined his remarks to the question of treatment. Increased intracranial tension was brought about by traumatic œdema or hæmorrhage, or a combination of both. Œdema resulted in a general enlargement in the size of the brain which tended to bring its surface close up against the dura. The effect of this was to hinder in varying degrees the absorption of the cerebro-spinal fluid into the venous sinuses, but as the cerebro-spinal fluid continued to flow from the choroid plexuses and accumulated in the ventricles and basal cisternæ, more and more pressure was brought to bear on the medulla until it became paralysed. In some cases, therefore, traumatic œdema resulted in death from medullary compression, and this was a fact that could not be overlooked from the point of view of treatment. Lumbar puncture afforded an easy means of reducing the tension, and was practically free from danger in cases of head injury, excepting in the stage of shock. As long ago as 1905, Quincke pointed out that in brain injuries the estimation of the cerebro-spinal fluid pressure was of importance, and that the best results were obtained by drainage. Until recently little importance had been paid to the principles underlying this observation. A rise of blood pressure accompanying intracranial tension was true only of the late stages of medullary compression, and should not be relied upon as an early sign. The only sure guide to the tension of the cerebro-spinal fluid was the manometer. The normal reading of the cerebro-spinal fluid pressure lay between 6 and 8 mm. of mercury. When the stage of shock following a head injury had passed, and no immediate surgical interference was called for, lumbar puncture should be performed and the tension of the fluid measured. If this was raised, sufficient fluid should be allowed to drain away until the tension was reduced to just below normal. The puncture should be repeated at the end of 12 hours in any case of severity, and performed daily until the tension returned to normal. If after two or three punctures it was found that the tension was increasing, then the possibility of cerebral decompression should be considered.

Dr. G. RIDDOCH (London) said that it was important to separate anxiety states from those of post-traumatic defect. The latter were of the order of a mild dementia—deterioration of general mental capacity. The patient's symptoms tended to become worse towards the end of the day, whereas in anxiety states the symptoms were usually most pronounced in the morning. The symptoms were mainly those of lack in mental and physical efficiency and were an indication of the effect on the brain as a whole rather than a sign of local contusion. Mr. Trotter had suggested the term "post-contusional submentation" to indicate this condition. Dr. Riddo considered that hypertonic saline was of value relieving intracranial tension, but that the meth should be used with discrimination; it should given preferably per rectum.

Dr. E. MAPOTHER (London) was surprised th various speakers whose experience of head inju was larger than his own should have found acu and severe psychoses so rare a sequel of head injur He described three such cases directly followi severe motor-car accidents. The salient feature all three was a manic state, a joyous satisfactio with self and circumstances and disjointed hype activity. This was associated in a manner that o did not see in ordinary mania with confusio Disorientation and amnesia for current events w also present; in fact, all three cases somewh resembled a combination of mania with Korsakow syndrome. All the patients recovered within a fe months. Their condition was certainly not of pure emotional origin, and the patients had never show previously a neurotic or psychopathic disposition.

Dr. PICKWORTH said that the connexion betwee head injury and mental disease was found in loc or general cerebral anoxæmia or the results consequer upon inadequate removal of metabolic waste product There was a remarkable similarity in some of th mental symptoms which might occur in chron subdural hæmorrhage, simple anoxæmia an anoxæmia produced by carbon monoxide poisonin Almost any symptoms of mental disorder might b reproduced by this condition. A history of hea injury was by no means rare in mental hospitals.

Mr. GEOFFREY JEFFERSON (Manchester) added h testimony to the importance of the conditio of retrograde amnesia which Mr. Trotter ha mentioned. Another point was the anatomical bas of contusional states, be they recent or remot Histological study of fatal cases showed minu though widespread change. He believed that lesio of a similar but lesser degree existed in those patien who finally recovered. The outstanding feature the finer changes in the brain tissue was cerebr œdema, so that the perivascular sheaths we distended or ruptured. The question of treatme was based largely on pathological anatomy and i physiological results. If gross hæmorrhage w present the treatment was obvious. It was th œdematous cases which presented the chief difficult A great change had occurred in the surgical treatme of head injuries, a change from indiscriminate surge to one of almost complete conservatism. Mr. Trott had done a service in voicing his doubts as to wheth they were right in allowing patients to lie for lo in a condition of restless unconsciousness, and the could be no question that judicious surgery held place in treatment. If one could be sure that th brain was œdematous, hypertonic solutions (a 50 per cent. glucose rather than saline was preferabl should succeed. But if a temporary improveme was followed by relapse, decompression should done.

Dr. R. FAGER (Exeter) stated that during the w he had had the opportunity of studying a large numb of cases with mental symptoms of varying degr following head injuries. Headache was an almo constant and distressing symptom; usually, but n invariably, it was referred to the site of injury, a was aggravated by stooping. The pain might be depressing in character that the patient sought refu in alcoholic bouts and even suicidal attempts. Oth common symptoms were restlessness, irritabilit lack of concentration, and even hallucinations.

Epilepsy occurred four times more frequently severe injuries than in those of a superficial charact Cases in which memory defect was a conspicuo feature were mainly in the frontal region, but the appeared to be no relation between the degree amnesia and the severity of the injury. Men symptoms were the direct result of the head inju in a small proportion of cases.

Early Treatment of Psychosis in Psychoneuroses.

Dr. Helen Boyle (Hove) said that the discussion vided itself naturally into two parts: (1) the early eatment of the individual, and (2) how we could st obtain it. It must be recognised that insanity gan before a person was insane. Many, if not most, the difficulties met with in education, criminology, ligion, industry, and general medicine, could only solved with the aid of mental medicine—an under-anding of the mind of man, in health and disease. o doctor would admit that an understanding of e body in health was foreign to his purpose of appling with disease. No doctor should any longer lmit that an understanding of the mind in health as redundant, and still less of the mind diseased. he intricacies of its connexion with the body still eeded further elucidation. The early treatment of cent cases in mental hospitals had improved mmensely of recent years. The hospitalisation of ylums was progressing apace, but she wished to nsider not the certifiably insane treated in mental spitals, but the patients whom it was harmful to rtify or who were uncertifiable, the large number the maladjusted, the patients labouring under sessions, phobias, inhibitions, and so on. These ere the cases for whom early treatment was so cessary if they wished to prevent the faulty ljustments, criminals and others. Dr. Carswell as the pioneer who started wards for borderland tients in connexion with the poor-law, Dr. oyle believed, in 1904. The Lady Chichester ospital was the first hospital for these cases, and arted in 1905. The pioneer in providing out-tient facilities was the late Dr. Rayner, who with ergy and foresight, about 1889, induced the vernors of St. Thomas's Hospital to open an out-tient department for early mental cases. Since en, many others had followed suit.

Still earlier than those cases they had been nsidering were the children who show maladjust-ents in school life or before, and for them the child idance clinics offered useful help. They are, as fore stated, the first line of defence. Two are ready in existence in England, and an elaborate e in London is being planned with American lp.

Finally, Dr. Boyle said that she would suggest at it was desirable: (1) that every general hospital ould have facilities for treating early nervous and rderland patients; (2) that child guidance clinics ould be available for the young maladjusted ildren and be under the charge of doctors; (3) that linquents should have expert examination with gard to their mental adjustment—on the first fence—repeated if necessary; (4) that voluntary arders be allowed in county mental hospitals;) that early insane patients should be able to be eated on two doctors' certificates; (6) that voca-nal guidance should be available for all who wish —as at the National Institute for Industrial sychology—as a preventive measure against mal-ljustments and unrest; (7) that every medical udent should be obliged to devote some time to e study of all forms of mental disorder; (8) that amining boards should require evidence of know-dge of all forms of mental disorder. It was better pay for this than for insanity, delinquency, nemployment, and industrial unrest.

Prof. Weygandt said that one of the chief difficulties as the recognition of pre-morbid cases. In the mmoner types of mental disorders there was inherited predisposition—e.g., schizophrenia, clothymia—and even in early youth latent mptoms might exist. These it might become ssible to detect by biological and psychological ethods. There had already been several attempts investigate children liable to mental disorder. Hamburg they had a clinic for the observation d treatment of psychopathological boys by specially ained medical men and teachers.

Dr. Wile said that the prevention of psychoses and psychoneurosis should be undertaken in childhood to be adequate. From experiences at his own clinic at the Sinai Hospital, New York, he had found that much of the work could be carried out in an out-patient department. The problems met with could be classified under the following headings: (1) social maladjustments, which grew out of social nonconformity; (2) inadequate and undesirable habit-formations—e.g., insomnia and night terrors; (3) personality trends—e.g., timidity, selfishness, and seclusiveness.

Dr. Mapother agreed that in smaller country towns an out-patient department or a ward might be all that was attainable, but it did not follow that such an arrangement was the ideal. In advocating the psychiatric clinic wherever possible as against the policy of a ward or department in a general hospital, he laid stress on points: (1) that it was wise not to rationalise into laws of nature restrictions and separations and vested interests which had really grown up from the absurdities of the Lunacy Act of 1890; (2) the tendency of every progressive country in Europe was towards establishment of special clinics; (3) detailed knowledge of attempts in Great Britain to establish psychiatric treatment in general hospital wards was evidence of their inadequacy.

Dr. Barkas said that it was too often assumed that early and recoverable cases were necessarily mild ones, not needing the resources of a mental hospital for their treatment; this was far from being the case, for it was just those eminently recoverable acute cases who broke down rather suddenly, without such prodromal signs as were likely to be noticed, who formed the group in which prognosis was best, while those of more insidious onset were, unfortunately, quite often the most intractable. An extension to all patients of the provisions now available for private patients, with adequate supervision by the Board of Control, a thing no general hospital was likely to welcome, would do much to supply all that was needed for the present. Child guidance clinics had shown how greatly the problem of the psychopathic child was bound up with social considerations, and how all-important was the social worker in the re-education of the family. The same applied to the adult neurotic; and Dr. Barkas believed that no clinic for either in- or out-patient treatment would be able to do satisfactory work unless it included a well-trained staff of social workers who could deal with the environment of the patient.

Dr. R. G. Gordon (Bath) considered that an intensive study of the personalities of individuals was necessary whether sound or sick, and that particular attention should be paid to the capacity and success enjoyed by adjustments to environment. If this was done he suggested that it would be found that the person who under certain conditions, whether of toxæmia, endocrine disturbance, mental conflict or emotional shock, broke down into a psychosis, differed in his "personality make-up" from another patient who under similar conditions developed a neurosis. Moreover, he would suggest that one of the chief differences was, that in the first case the personality had no real tendency to adjust to the environment, and that in the present state of our knowledge our efforts scarcely increased this adjustment. With greatly increased knowledge we might be able to foresee that under certain circumstances which might be avoided, "A" would break down into a psychosis of a particular kind, say manic-depressive insanity; "B" into a psychosis such as dementia præcox, and so on; while "X" would break down into a neurosis of a certain kind, say, an anxiety state; and "Y" would develop hysteria, and so on. He could not affirm too strongly that this was an ideal situation, and that at present probably no one pretended to be able to carry out such subtleties in diagnosis; yet increasing experience seemed to be pointing that way.

Dr. J. R. REES (London) said that there were comparatively few who realised that the moral disorders, the character and personality defects of childhood, were the forerunners of much of the mental disorder of later life. Psychology should be studied in the nursery and in the infant school, and the general practitioner was the ideal person to tackle this early period. He had the entrée to homes and the confidence of patients. He asked if the B.M.A. could not initiate a campaign of education. The mental hygiene movement in America did a vast and altogether admirable work which was practically left untouched in this country. The general practitioner, with his experience and balance, was well able to get hold of the essential facts that were known, and would in consequence be infinitely better equipped to deal with the earliest manifestations of trouble and to do preventive work of inestimable value. Clinics, early treatment centres, and child guidance centres must come, and it seemed to him essential that the profesion should have adequate knowledge if it was to coöperate adequately with these specialised institutions.

Dr. GOODALL (the President) said the delay in dealing with the recommendations of the Royal Commission on Mental Disorders in respect of facilities for early treatment was deplorable. He detailed the arrangements at Cardiff for dealing with early cases in an out-patient department of the Cardiff Royal Infirmary during the past seven or eight years. Dr. Goodall stated that the 30 to 40 per cent. of patients amongst the direct admission to the Cardiff Mental Hospital who were annually discharged within six months of admission could—the majority of them—be treated at a psychiatric clinic, quite apart from the lunacy laws as at present constituted, and all the drawbacks which those laws implied. His constant advice to the Cardiff Local Authority was to rigidly abstain from any addition to their mental hospital, and to concentrate upon provision, in conjunction with the Cardiff Infirmary, of a fully-equipped clinic in psychiatry.

Dr. DORIS ODLUM (London) desired to emphasise most strongly that the provision of a psychiatric out-patient department in association with a general hospital was most valuable, not only in the interests of patients, but also as a means of educating the public, nurses and doctors in other departments of the hospital. Adequate social service in connexion with such a department, and specially trained welfare workers were also essential.

Dr. W. A. POTTS (Birmingham) said that the two most important centres for early treatment to be carried out were: (1) the infant welfare clinic, which provided the earliest opportunity for the examination and training of the child; (2) the antenatal clinic, where the attitude of the mother, and also of the father, to life, and also to the child, might be investigated, and, if necessary, adjusted. It was necessary to correct any misunderstanding that might arise from what was said about the damage of a sentimental attitude towards delinquents, by saying that those who were engaged in work with delinquents were out for justice, and for an opportunity for developing and drawing out the diminished sense of responsibility many delinquents had.

Dr. R. S. ALLISON (Ruthin) referred to some physical aspects of the treatment of the psychoneuroses. From the physical standpoint the first essential after a careful history was a thorough physical examination, and following this, investigations along bacteriological, biochemical, and radiological lines. The object in making these investigations was twofold: (1) the search for toxic foci, (2) to ascertain the physical peculiarities of the patient. The teeth, the throat, the accessory sinuses of the nose, the appendix, the gall-bladder, the colon, the urine and fæces were commonly the sites of a latent infection. In many cases this might be only detected after a thorough investigation of the case.

Dr. C. FORBES (Aberdeen), speaking as a gener practitioner, desired to support strongly Dr. Ree suggestion regarding the education of the professio The proposition should be urged by all who we interested in the early treatment of mental a nervous illness. There was a definite need for t institution of clinics as a medium not only of resear and treatment, but also for the education of fami doctors in the particular area served.

SECTION OF TUBERCULOSIS.

RELATION BETWEEN TRAUMA AND TUBERCULOSI

Mr. H. MORRISTON DAVIES (Ruthin) was in t chair, when Dr. NORMAN TATTERSALL (Leed read a paper on the relationship between traun and tuberculosis from the physician's standpoir He considered that inoculation tuberculosis, such butchers' and pathologists' warts, and acute gener ised miliary tuberculosis following such injuries as blow on a tuberculous testis, forcible movement a tuberculous joint, and operations on tuberculo glands came into the category of traumatic tube culosis. In 300 cases of pulmonary tuberculosis found six cases in which trauma was suggested the exciting cause, and in four of these, very defini symptoms had bridged the gap between the inju and the onset of the pulmonary lesion. He regard as satisfactory Parkes Weber's classification of su cases into (1) those in which no tuberculosis w suspected prior to the injury, and (2) those in whi tuberculosis was known to exist before the accide An injury rarely produced a state of lowered resis ance to the implantation of tubercle bacilli, and t more probable explanation was that the injury h activated an existing focus of disease. To suppo this contention he instanced the work of Opie a others who had isolated tubercle bacilli from gla and lung tissue which showed no naked-eye eviden of tuberculosis. Further, accidental wounds tuberculous patients healed readily. Although inju to the chest might give rise to any form of pulmona tuberculosis, the disease did not necessarily start the same side as the injury. Compression injuri were more potent in exciting pulmonary tuberculos than penetrating wounds. The course of the disea subsequent to injury might be acute, subacute, chronic. Such symptoms as pleurisy and hæmoptys were of great importance in fixing the date of ons but it was very important in the assessment of clai for compensation that "bridge" symptoms shou be present between the injury and the diagnos He suggested the following questions as helpful arriving at a decision.

1. Was the patient actively or passively tuberculous bef the accident, and if the former, what was his expectati of life?
2. Is the fact of injury definitely established, and was of such a nature as to be likely to damage an active quiescent lung focus?
3. What period of time elapsed between the injury a the diagnosis, and was the period covered by brid symptoms?
4. Is the present condition of the patient and the cou of the disease such as might be expected if the injury h reawakened or aggravated an existing latent focus disease?

Mr. ROBERT MILNE (London), in discussing t question from the surgeon's point of view, said th whereas trauma may lead to a wound and to t implantation of tubercle bacilli in the damag tissues, weakness from unsuspected tuberculosis, for example in the knee-joint, may also lead to accident. In some cases trauma may give rise to infection of the injured part with tubercle baci from the blood stream, but, in his opinion, t percentage of such cases usually given (30 per ce according to some authors) was much too high. I would put it as low as 2 to 5 per cent. Mode diagnostic methods had shown that many of t so-called tuberculous lesions following trauma we

stances of non-tuberculous conditions such as betic spine, chronic traumatic arthritis, Kümmell's sease, Perthes's disease, *pied forcé*, fibro-sarcoma of e femur, &c. He illustrated these and other nditions by a series of lantern-slides. In conusion, he said that injury to a tuberculous joint d lead to recrudescence of the disease, but emphaed his opinion that trauma was not a common use of tuberculosis in cases where a quiescent cus had not previously existed.

Dr. OTTO MAY (Prudential) dealt with the matter om the point of view of accident insurance. He reed with most of Dr. Tattersall's statements. r. Milne, he said, had shifted the discussion to nother plane, and had maintained that we must uestion the diagnosis of traumatic tuberculosis in arly every case. But the employer is still liable r compensation claims whether the condition is berculous or not, so that, in compensation cases, e exact diagnosis was not really a matter of first portance. Dr. May classified traumatic tuberlosis for the purposes of accident insurance and mpensation under four headings: (1) recrudescence a pre-existing focal lesion; (2) miliary tuberculosis llowing trauma at the site of a tuberculous focus disease; (3) tuberculosis arising at the site of an jury without a history of previous tuberculosis; and) cases in which pulmonary tuberculosis arises after injury to some other part of the body. In a court law, he said, one can only give an opinion as to e possibility of the accident having caused the sease, but provided that one did not assume the se of pontificial infallibility, a touch of dogma was more practical help in the dispensation of justice an the cleverest exposition of scientific agnosticism.

During the discussion which followed the reading the papers, Sir ROBERT PHILIP (Edinburgh) ggested two practical points in dealing with accident ses. In the first place, a series of radiograms the affected parts and of the chest should be taken short intervals and, secondly, many patients had use to bless the accident, because it brought a nouldering tuberculous focus into view, and by rly treatment and the care that was taken in mpensation cases, many valuable lives were saved. Dr. ALEXANDER BROWNLEE (Cardiff) thought that e percentage of cases following injury was higher an the figures given by Mr. Milne. In a series of s own cases he had found 32 per cent. of cases of p disease, 33 per cent. of spine cases, 22 per cent. knee cases, and of other joints 25 per cent. gave history of injury. He agreed that it was doubtful nether trauma to a previously healthy person uld set up tuberculosis in the injured part, but ought that probably the majority of the population s pathologically, although not clinically, tuberlous. "Bridge" symptoms were important in mpensation cases, especially if occurring within months following injury to the knee, within months after trauma to the hip, and in the case the spine, within two years. However, one could t dogmatise on this point.—Dr. CECIL WALL ondon) said that repeated multiple minor traumata, tigue, and mental anxiety could all help in the tivation of a dormant tuberculous focus. There s little difference, he said, between minor multiple umata and fatigue.—Dr. JAMES CROCKET (Glasgow) garded both mental and physical strain as instruental in exacerbating tuberculosis.—Dr. H. V. NTOR (Cheshire Joint Sanatorium), in discussing berculosis following war injuries, said that the nistry of Pensions did not consider claims in cases gnosed as tuberculous within the last two years.

Dr. TATTERSALL, in reply, said that he was gratified at a blow had been struck against the theory that berculosis was implanted on injured previously althy tissues. In reply to Dr. Cantor, he said at the Ministry of Pensions had been very generous their treatment of ex-Service men.—Mr. MILNE l not agree with Dr. May that the diagnosis was not important in compensation cases. He regarded it as essential both from the point of view of treatment and of compensation.

FACTORS IN THE BIOCHEMISTRY OF TUBERCULOSIS.

Dr. L. S. T. BURRELL (London), in reading a paper on the therapeutic value of the heavy metals in pulmonary tuberculosis, referred briefly to the use of copper and lead, and to the reactions following the use of such metals as well as of other shock-producing agents such as serum, tuberculin, protein, sun rays, &c. In the use of gold, and especially of sanocrysin (double thiosulphate of gold and sodium) he emphasised the point that the reaction following an injection was similar to that produced by the other shock-producing agents, but that it differed from them in its effect, in that the reaction was followed by the disappearance of tubercle bacilli from the sputum, and by diminution in the amount of sputum. The chief indications for the use of sanocrysin were (1) in cases where the amount of sputum containing tubercle bacilli persisted in spite of other forms of treatment, and (2) in cases of bilateral disease, where it could be used in conjunction with artificial collapse of the more extensively diseased lung. He usually commenced with a dose of 0·1 g. followed three days later with one of 0·25 g. Then, at weekly intervals, he gave doses increasing from 0·5 to 1 g. until the patient had had 5 or 6 g. The complications, such as albuminuria, a metallic taste in the mouth, stomatitis, erythematous rashes, and febrile reactions, had not been serious or of frequent occurrence. In conclusion, he said that he regarded sanocrysin not as a specific against tuberculosis, and certainly not as a cure, but as a useful addition to other methods of treatment.

Dr. J. CLIFFORD HOYLE (Cambridge) read a paper on the serum calcium in experimental tuberculosis. Changes in the calcium metabolism had long been recognised to be associated with tuberculosis, and earlier observers had maintained that "demineralisation" occurred during the disease. No sound evidence existed for the belief that decreased calcium retention took place in tuberculous infections, except possibly in the terminal stages. This fact could probably be explained as being due to infection with secondary organisms. To support this view he gave the results of some interesting experiments carried out on rabbits. He had observed a striking difference between the serum calcium estimations when intraperitoneal as opposed to subcutaneous inoculations of bovine tubercle bacilli had been made. In the former the disease became generalised without an ulcer at the inoculation site, and in these cases little change was observed in the serum calcium curves, but in the latter where an ulcer infected with secondary organisms formed, the serum calcium fell steadily. If the ulcer healed, as sometimes happened, the serum calcium rose again, even while the generalised disease became steadily worse. Septic infection in previously normal rabbits also produced a considerable fall in the serum calcium.

Dr. W. H. TYTLER (Cardiff) gave the results of his work on the "tuberculin-active fraction of the tubercle bacillus." He referred at length to the work of previous observers, especially of Long and Siebert. His own work had been primarily concerned with the production of a highly active preparation for experimental work. His methods of preparation were, in principle, similar to those of other workers, and his product was not a newly discovered substance, but was a highly active fraction with some practical application. The substance, obtained by the method of which he gave full details, was non-dialysable, and consisted of protein with a small admixture of proteose. Then nitrogen content varied from 11 to 12·5 per cent. The active fraction used for skin reactions gave a more sharply defined reaction than tuberculin, particularly at low concentrations. It might be stored in dry form, was accurately

measurable by weighing, and was stronger than old tuberculin. He had no reason to believe that it would have any greater therapeutic value than tuberculins in general.

In the afternoon Mr. MORRISTON DAVIES and Mr. TUDOR EDWARDS gave a demonstration of the results of thoracic surgery, and later, at the Cardiff Royal Infirmary, showed a series of patients on whom thoracoplasty had been performed. Dr. PARRY MORGAN (Cardiff) showed his artificial pneumothorax apparatus fitted with a double manometer.

AFTER-EFFECTS OF SURGICAL PROCEDURES IN PULMONARY TUBERCULOSIS.

Mr. TUDOR EDWARDS (London) opened the discussion by reading a paper on the after-effects of surgical procedures in cases of pulmonary tuberculosis. He regarded the after-results as being due to a series of factors such as: (1) the right choice of cases, (2) the type and extent of the operation, (3) the anæsthetic employed, (4) the operative mortality and complications, and (5) the after-treatment. In discussing the choice of cases for operation, he said that the chief factor was the condition of the "better" lung, which should show no active disease for at least three months prior to the operation. In cases of doubt it was his custom to perform a preliminary phrenic evulsion on the more-affected side in order to test the capacity of the better lung to withstand the increased strain to be placed on it. In his experience there was a tendency to wait too long before the surgeon was called in. The chances of recovery by surgical measures diminished with the increase of the amount and activity of the disease in the lung. Surgical procedures in diseases of the chest had incurred a certain amount of unnecessary odium mainly on that account. Experience had convinced him that adequate collapse of the affected lung could be obtained by a preliminary phrenic evulsion and a subsequent two-stage thoracoplasty from the first to the tenth ribs posteriorly. In order to produce localised collapse, phrenic evulsion and pneumolysis were satisfactory operations. In tuberculosis, however, it was usually necessary to secure complete collapse. The best anæsthetic was a gas and oxygen combined with local anæsthesia. The operative mortality and the complications of thoracoplasty such as shock, pulmonary embolism, spread of disease in the opposite lung, and septic infection of the wound could be largely diminished by careful pre-operative and after-treatment. No complications had occurred in his cases of phrenic evulsion and apicolysis, nor had they required much in the way of after-treatment. In thoracoplasty, after-treatment is essential, an important feature being that the patient should spend from three to six months under sanatorium régime.

Dr. F. G. CHANDLER (London), in discussing the question from the physician's point of view, said that a physician, in recommending a serious operation, took a great vicarious burden on himself. He should ask himself the question, "Would I, if necessary, have this operation performed on a member of my family or on myself?" The surgeon's relationship to the patient was, in a sense, impersonal, and it was the physician who had to consider the operative risk, the possibility of after-pain and discomfort, and the ultimate result. In chest surgery there were peculiar difficulties. Problems of judgment arose as well as questions of technical skill. If it were possible, a combination of the physician-surgeon would be ideal, and there were indications that developments along these lines were taking place. The open operation for dividing pleural adhesions was, in his experience, usually followed by sepsis and empyema, although there was little disturbance from the actual operation. In phrenic evulsion the immediate risk was small, but some complications, such as hæmorrhage, hæmoptysis, air embolism, chylous fistula, pulmonary œdema, and injury to other nerves had been reported. He agreed with Morrist Davies that the operation was of undoubted val in basal tuberculosis and as an accessory operation artificial pneumothorax. Apicolysis and pneum lysis were, from the physician's point of view, t operations of choice. The shock, after-discomfo and operation mortality were negligible. A sat factory packing substance had still to be found, b he was greatly interested in the possibilities of th operations. It was difficult to judge the mer of thoracoplasty, on account of the extremely varia results. The after-results could not be usefu discussed without a clear idea of the criteria suitability and non-suitability. Of the cases suita for the operation, he gave the following types: If a successful artificial pneumothroax had been allow to terminate with a recurrence of symptoms a re-collapse was not possible; (2) if an artificial pneum thorax was imperatively indicated in a case of p gressive unilateral disease, yet by reason of adhesio it was not possible to induce one; (3) if chro unilateral disease was present causing distressi symptoms. The cases not suitable included: those in which there was a suspicion of active progressive disease in the "better" lung; (*b*) th in which the general resistance was poor; (*c*) th with fibroid phthisis with every prospect of a reas ably healthy life; and (*d*) cases with amyloid disease tuberculous ulceration of the intestines. The ope tive mortality varied between 5 and 12 per cent., t after-pain and distress were frequently considerab but the results of the operation were, on the wh good. Surprisingly little deformity was produc The result could not be guaranteed, but in some ca there was a prospect of complete and permane recovery which no other method of treatment co procure. Oleothorax, although our experience it was limited, would probably be of great value preventing obliterative pleurisy in artificial pn mothorax.

Dr. D. W. FENWICK JONES gave the results of cases of thoracoplasty carried out at the North Wa Sanatorium. His general impression was, that wh it was a desperate operation in advanced cases, was a pity that cases of earlier disease were n selected for the treatment.—Dr. WALL said that t last stronghold of the physician had been taken the surgeon, but he agreed that the results of ch surgery were good, and he looked forward to t establishment of the chest specialist who would both a physician and a surgeon.—Dr. D. A. POWE (Cardiff) remarked that we were at the beginn of an important operative era, in which speciali would be regional, and not divided into medic and surgery. He was somewhat disappointed w the results of artificial pneumothorax, and hop that those of thoracoplasty would be better.—M MORRISTON DAVIES, in showing a series of pho graphs and radiograms of cases of thoracoplas pointed out in the photographs the negligible defor ity as compared with radiograms of the same ca showing extensive collapse of the lung and t chest-wall. He regarded the one-stage operation better than the two-stage, because the pulmon collapse obtained was more complete, and a because the patient did not have to face the anxi and shock of two serious operations. He plead for the establishment of operating theatres in sa toria, and thought that in this respect the exam of the Welsh Memorial Association might well followed.

Mr. EDWARDS, in reply, said that after-pain w largely due to bad technique. An operative mortal of 12 per cent., taking everything into account, w not excessive.

TUBERCULOSIS AS SEEN BY THE GENERAL PRACTITIONER.

Dr. ANGUS KENNEDY (London), in opening t discussion, said there had been a surfeit of laudati about the success of the campaign against tub

ulosis. In his opinion, the expenditure of time and money had not been justified. The mortality from uberculosis in 1821 was 25 per cent., in 1871, 12 per cent. So that, at a time when no preventive measures had been taken, the mortality had fallen to alf. Since then, with the advent of the campaign, he mortality had fallen only 3 per cent. He explained his as being due to the fact that tuberculosis was an pidemic disease and that, as in all epidemics, the irulence of the bacillus had been greatly attenuated ntil the disease was now very mild, and in fact ndemic. In 50 years' time it might again become pidemic. Immunity in his opinion was inherited, nd by way of illustration he cited his experience mong negroes who had come to the East-end of ondon. In one half-caste family he had observed hat the boys, who all had a touch of the "tar-brush," ied from tuberculosis, whereas the girls, who had nherited mostly the characteristics of the white arent, were still alive. We should aim at producing race immune from tuberculosis. Before people narry they should look into the family history as ell as into the banking account.

Dr. R. CAMERON (Cardiff) said that early diagnosis as sometimes tragically simple, and in other cases xceedingly difficult. He pointed out that in Cardiff, uring 1926, 527 fresh cases of tuberculosis had been otified and that the number of deaths from the isease was 288. These figures were relatively mall, as during the year no serious influenza epiemic had occurred. After giving other interesting etails as to the prevalence of the disease, and the ousing conditions, together with the number of ontacts, he proceeded to the detailed account of he early diagnosis of pulmonary tuberculosis, basing is description on Pottenger's classification of the ymptoms into pulmonary, reflex, and catarrhal. Ie next emphasised the diversity of the modes of nset of pulmonary tuberculosis, and finally discussed he various methods of physical, laboratory, and adiographic examination. The tuberculin tests were ot, he considered, of practical value to general ractitioners.

Dr. J. R. GILLESPIE (Belfast) thought that the ubcutaneous tuberculin test, but not Pirquet's skin eaction, was of great value in diagnosis. During he past 15 years he had found 300 cases giving negaive results to the test, and of these only five subseuently developed tuberculosis. It should be emembered that a negative tuberculin test did not ıean that the patient would be immune for life.

Dr. AMBROSE OWEN (Aberdare) agreed with Dr. Kennedy that tuberculosis was on the decline, but e thought that public health measures had done ıuch to decrease the incidence of non-pulmonary uberculosis. Epidemics of other diseases such as ıfluenza were largely instrumental in increasing he incidence of pulmonary tuberculosis. Contrary o Dr. Kennedy's opinion, he found phthisis more cute than it was 15 years ago. Pleurisy and æmoptysis were not always indicative of tuberulosis. Hæmoptysis especially was a frequent omplication in epidemic influenza. A striking fact as that hæmoptysis occurred in phthisical and on-phthisical patients during the same seasons, nd in the former was often due to secondary ıfections. Our failure to control the great epidemics ffecting the respiratory system was one of the easons why phthisis was still so rampant.

Dr. R. J. MATTHEWS (Newport) pointed out the ontrast beyween tuberculin reactions in the urban nd rural populations. The former gave positive nd the latter negative reactions in most of the cases e had tested.

Dr. KENNEDY, in reply, said that we could only ıdge the results of treatment by statistics. Epiemics ceased owing to the attenuation of the germ nd to the elimination of the susceptible people by eath. By keeping alive those susceptible to tuberulosis, we were doing our own progeny a grave ıjustice.

EXHIBITION OF DRUGS, SURGICAL INSTRUMENTS, FOODS, AND APPLIANCES.

(Concluded from p. 302.)

SURGICAL AIDS; HOSPITAL AND LABORATORY EQUIPMENT.

[21] The Denver Chemical Manufacturing Co. and [25] The Thermogene Co., Ltd. (Haywards Heath, Sussex, and Victoria Embankment, E.C. 4), displayed their well-known "Antiphlogistine" and medicated wadding respectively for the few who are not already convinced of their value.—[53] Baird and Tatlock, London, Ltd. (14–15, Cross-street, Hatton-garden, E.C. 1), from a large selection of bacteriological, pathological, and physiological apparatus, selected for special attention an incubator with a patent registered regulator; Kahn's outfit for the precipitation test of leprosy and syphilis; and Horrock's outfit for detecting chemical poisons in water.—[79] British Distribution Co. (52, Mortimer-street, W. 1) demonstrated the "Camp" physiological supports, embodying certain patent adjustments designed to give correct anatomical support without undue constriction and with the required pressure and uplift. Special models shown were the "Camp" ptosis support for gastric or intestinal prolapse; "Camp" visceroptosis support, giving a flattening yet upward-cupping effect, and "Camp" post-operative supports.—[29] R. H. Dent (309, Oxford-street, W. 1) had devised several new features of the "Ardente Aid for the Deaf." The wrist-watch pattern, shown last year, has been followed by the "hat-button," which can be pinned inside the lining of a hat and is remarkably inconspicuous. The latest stethoscope is smaller than its predecessors, can be used monaurally or binaurally, and gives a very clear enhanced sound with complete absence of electrical noises.—[35] Fassett and Johnson, Ltd. (86, Clerkenwell-road, E.C. 1), were showing again the well-known Mead's rubber adhesive plaster, and Seabury's "Gold Cross" absorbent cotton, as well as plasters, ligatures, and bandages.—[85] General Acoustics, Ltd. (77, Wigmore-street, W. 1), drew special attention this year to the new "Dime" earpiece, about the size of a sixpence and weighing two ounces, worn without head-band or crook, and leaving the hands free. The midget battery is very powerful and gives no distortion.—[15] Theodore Hamblin, Ltd. (15, Wigmore-street, W.1), showed ophthalmic instruments and equipment, including the Lister-Morton luminous ophthalmoscope; a new children's astigmatic test by Mr. E. E. Maddox; the Lawson self-contained operating lamp for use where no electric current is available; and a special display of telescopic spectacles for operating and for low visual acuity.—[13] Charles Hearson and Co., Ltd. (68, Willow-walk, S.E. 1), showed a wide range of incubators, ovens, stills, centrifuges, and other laboratory equipment, including the "Hellige" comparator for estimating pH values; a new "Klett" top-reader colorimeter, and several new Reichert microscopes, especially a monobinocular one on a new principle. This firm has opened a new show-room at 27, Mortimer-street, W. 1.—[40] Hoskins and Sewell, Ltd. (Bordersley, Birmingham), emphasised the usefulness of the new patent castor-pad action for allowing the bedstead to stand firm on rubber pads or to be wheeled on castors. They also showed the Nottingham Children's Hospital wheeling cot; the S. P. Smith's extension fittings with side attachment for abductions, by which any and all fractured limbs can be fixed; and several other bed attachments and screens.—At Stand [56], The Inhaling Drug and Apparatus Co., Ltd. (30, Grosvenor-place, S.W. 1), we learned that even insulin may now be administered by inhalation therapy, while excellent reports have been received of the use of the Spiess-Drager drug nebulising and inhaling apparatus in the treatment of tuberculosis and whooping-cough, as well as asthma and other lung conditions.—[64] Short and Mason, Ltd. (Atlantic House, 45–50, Holborn-viaduct, E.C. 1), demonstrated

the familiar "Tycos" sphygmomanometers, thermometers, and barometers. The new automatic recording type will be on the market shortly.—[92] Simco, Ltd. (22–28, Shand-street, S.E. 1), showed a range of beds which contain no cast iron, and are, therefore, unbreakable, especially an adjustable fabric-bottomed bed in which the patient can be put into any position with a minimum of effort. The universal bottom can be fitted on any ordinary bed frame, and is, therefore, extremely convenient for home nursing.—[4] Spencer Corsets, Ltd. (Banbury, Oxon), stressed the fact that each garment made by them is designed for each individual patient from exact measurements by a trained corsetière. They drew particular attention to their sacro-iliac corset and abdominal supporting corset for visceroptosis and pregnancy.—[48] John Weiss and Son, Ltd. (287, Oxford-street, W. 1), had a display of surgical instruments, including many new models and modifications, and a great number in stainless steel. The display included thyroid and cystoscopic instruments, and Bishop Harman's scotograph.—[90] Whitfield's Bedsteads, Ltd. (109–125, Watery-lane, Bordersley, Birmingham), showed improved "Lawson Tait" fracture, epileptic, cardiac, and obstetric bedsteads, drawing attention to the fact that the double wheeling foot-end can be let down on to wood blocks when the bed is wanted steady. The obstetric pattern has nickel-plated crutches and a winding-up frame.

X Ray, Light, and Heat Apparatus.

[78] The Dowsing Radiant Heat Co., Ltd. (91–93, Baker-street, W. 1), showed samples of many modern appliances for the application of the Dowsing treatment, ultra-violet lamps, and electric radiators of all kinds, particularly an expanding radiant heat apparatus which can be used for both legs or the abdomen or a single limb.—[91] Philips Lamps, Ltd. (145, Charing Cross-road, W.C. 2), introduced the "Metalix-Portable," a new compact apparatus for the general practitioner, which packs into a suit-case, stands on adjustable telescopic legs, plugs into any wall fixture, and is absolutely shock-proof. There was also a new deep therapy tube for operation at 220,000 volts.—[77] The Solus Electrical Co. (100, Judd-street, W.C. 1) showed a 30-M.A. X ray transformer set, complete with all-metal control table; the Solus-Jarhns Potter-Bucky motor-driven revolving grid, with special centring device; the valve-rectified "Solustat" apparatus; an air-cooled double-gap diathermy apparatus, and a great range of electro-medical and ultra-violet apparatus.

Books.

[5] Messrs. Baillière, Tindall and Cox (8, Henrietta-street, W.C. 2) exhibited English and American medical and scientific books from their own press, as well as those issued by a number of other firms.—[68] Messrs. J. and A. Churchill (40, Gloucester-place, W. 1) showed an interesting series of medical directories, from the small crown octavo of an inch thick, of 1846, up to the enormous eighty-fourth issue of last year. Among other books were Massie's "Surgical Anatomy"; the seventh edition of Rowlands and Turner's "Operations of Surgery"; the new Taylor's "Medical Jurisprudence"; the ninth edition of Cushny's "Pharmacology"; and the "Recent Advances" series, of which the latest are: "Diseases of Children," by W. J. Pearson and W. G. Wyllie; "Surgery," by W. Heneage Ogilvie; and "Tropical Medicine," by Sir Leonard Rogers—[72] William Heinemann, Ltd. (99, Great Russell-street, W.C. 1), included in their exhibit MacCormac's new edition of Jacobi's "Atlas of Dermochromes"; the second edition of Dan McKenzie's "Diseases of the Throat, Nose and Ear"; McDonagh's "Nature of Disease"; and Halls-Dally's "Low Blood Pressure."—[37] H. K. Lewis and Co., Ltd. (136 and 140, Gower-street, W. 1), had a number of convenient clerical aids for the practitioner, including a new roll-top cabinet for panel envelopes in one, two, three, or four sections, each holding 500; and a useful series of instruction slips for patients, giving printed details, for instance of how to prepare a fomentation, exercises fo constipation, after-care of dental extractions, an alkaline treatment of gastric ulcer. On the cover supplied for these slips are relevant reminders for th doctor. Among the books recently issued by th firm are "The Injection Treatment of Varicos Veins," by A. H. Douthwaite, third edition; " Shorter Anatomy" and "Anatomy for Artists," b E. Wolff; and "The Brain from Ape to Man," by D Tilney.—[89] The Oxford University Press (Falcon square, E.C. 1) showed text-books, manuals, and oth works, including "Gastro-Intestinal Diseases," fro the James Mackenzie Institute; the Robert Jon birthday volume; the fourth edition of Humphri "Artificial Sunlight"; and the second enlarge edition of Fairbairn's "Gynæcology with Obstetrics. —[16] John Wright and Sons, Ltd. (Bristol), showed large selection of books, including a new edition Herbert French's "Index of Differential Diagnos of Main Symptoms"; H. L. Tidy's "Index of Sympt matology"; C. P. Wakeley's and St. J. D. Buxton "Surgical Pathology"; and the "Synopsis" serie

Spas.

[94] Braceborough Spa (Lincs.) is already known valuable for skin affections, and its water is now beir prescribed for the treatment of latent infection The calcium content is very high: 30·39 grs. per gallo of calcium bicarbonate, and is, therefore, recommende for all forms of calcium deficiency, particularly infants.—[18] Harrogate (Baths and Wells Depar ment) has added to its already diverse waters "Fango a curative mud which has recently been discover near the axis of the anticline around which th peculiar geological formation of the Harrogate stra centres. The mud is radioactive, and contai sulphur.—[3] The Stanboroughs is the London hydr pathic establishment, and has excellent facilities f convalescent care and modern methods of treatmen

Miscellaneous.

[74] The Food Education Society (29, Gordo square, W.C. 1) displayed its dietetic books a pamphlets, including a number of Welsh edition The latest leaflet, entitled "A Salad a Day," giv arguments and prescriptions for salads. Mr. Hecht "School and University Diet" and "The Diet Brain Workers" were selling well, and another usef publication on show was "The Reform of Institution Housekeeping."—[86] The Hammond Varityper C Ltd. (75, Queen Victoria-street, E.C. 4), natural laid emphasis on the special medical keyboards f typing prescriptions, and also the mathematical a chemical formulæ keyboards and those especial adapted for writing in foreign languages.—[36] T Medical Insurance Agency (B.M.A. House, W.C. again recommended its valuable services, particular drawing attention to the charitable work it is able support both at Epsom College and for the orph daughters of medical men. Messrs. Mann, Egert and Co., Ltd., continue to act as consulting mot engineers to the agency.—[55] The Medical Sickne Annuity and Life Assurance Society, Ltd. (30 High Holborn, W.C. 1), offered its usual attracti policies to doctors and dentists.—[88] An unusual b very interesting exhibit was that of the Pentec High-pressure Casserole Cooker, shown by Philli and Proctor, Ltd. (125, High Holborn, W.C.1). this simple covered saucepan food is cooked under pressure of 45 pounds to the square inch. In this w the heat is greatly intensified, and any food can cooked in eight minutes. It is almost impossible overcook, and therefore a joint and vegetables can put in together, the pressure adjusted by a simp device on the cover, and when the whistle blows few minutes later all the contents will be fou equally cooked. In addition to the obvious domes advantage in saving time, worry, and fuel, there is dietetic advantage in that the starch-cells are mere swollen and not burst by this cooking and the "goo ness" is therefore conserved. The taste is certain

cellent.—[66] Radiation, Ltd. (15, Grosvenor-place, W. 1), showed an exhibit of gas-heated appliances dentists, and described by means of diagrams a ies of experiments undertaken in an attempt to prove the quality of the heat emitted by gas-grates d cookers by obtaining a softer and more penetrating ve-length.—[75] The "Vita" Glass Marketing ard (Aldwych House, W.C. 2) attended for the first ne to explain the properties and methods of fitting Vita" glass which, while transmitting a large propor- n of the ultra-violet spectrum, is indistinguishable m it in appearance, can be obtained from local ilders, and is entirely British.

CONGRESS OF RADIOLOGY.

STOCKHOLM: JULY 23RD–27TH, 1928.

THE Second International Congress of Radiology ich met in Stockholm from July 23rd to 27th, der the presidency of Prof. GOSTA FORSSELL ockholm), was attended by 962 members from countries. T.R.H. the Crown Prince and Prince arles of Sweden were present at the inaugural eting in the Concert House, when Prof. Forssell eived the presidential badge, a gift from the itish Institute of Radiology, at the hands of Mr. C. urstan Holland and Dr. Stanley Melville, respec- ely president and secretary-general of the First ernational Congress held in London in 1925. e President then opened a discussion on Teaching l Training in Medical Radiology, expressing his n conviction that radiology has become so important medical science as a whole, and so firmly established a department of that science, as to make a systematic sentation of the subject an essential part of the neral medical education. He was followed by Dr. BELOT, speaking for France, Prof. M. HICKEY, U.S.A., Dr. G. HOLZKNECHT, for Austria, Dr. LVILLE, for Great Britain, and others, all whose pers will be published in book form as a supplement *Acta Radiologica*. The sectional proceedings of the ngress took place in the Riksdagshuset, being ided into (1) Rontgen Diagnostics, (2) Rontgen l Radium Therapy, (3) Radiobiology and Helio- rapy, and (4) Radiophysics and Medical Radiology. ogether 225 papers were read, one of which we olished in our issue of August 4th (p. 221); stracts of several others follow. In the first section umber of papers dealt with opaque injections into in and spinal column for the diagnosis of tumours l other diseased conditions of the central nervous tem (encephalography and myelography), into ale genital organs (hysterosalpingography), into neys (pyelography and pneumopyelography), as ll as the use of contrast means in the examination the accessory sinuses of the nose. In the second tion the chief interest centred around the radium atment of malignant tumours and the X ray atment of nervous disease of different kinds— erculosis, goitre, and diseases of the skin. The anisation and the results obtained at Radium- mmet in Stockholm were illustrated by a demon- ation of some 100 patients. In the third section pers were read on the effect of light in various eases, the action of ultra-violet rays on cells and ues, and the therapeutic value of irradiated oils. e fourth section had two main themes on its gramme: (1) the establishment of an international t of dosage in X ray treatment, to which a leading icle was devoted in our columns last week; and the question how to obtain international regula- ns for protection in radiological work. The latter to the setting up of an international committee carry out with a few small alterations the recommendations of the British X ray and Radium Protection Committee. During the Congress the International Committee of Radiology met and appointed an executive committee consisting of Prof. Forssell, Mr. Thurstan Holland, Dr. A. Béclère, Prof. W. Friedrich, Prof. M. Haudek, Dr. G. A. Pfahler, and Prof. P. Tandoja, which fixed Paris as the place for the Third International Congress in 1931, with Dr. Béclère as its president. An exhibition in connexion with the Congress comprised apparatus shown by 45 firms, of which 24 were from Germany, 7 from England, and 5 from Sweden.

Rationale of Radiation Therapy.

Invited to contribute a paper on this subject Dr. ROBERT KNOX (London) dealt with the radiation treatment of certain diseases, arranged for convenience of reference in groups. In the cases treated, at one period or another, a degree of control was obtained by systematic dosage; to ascertain the nature of this control innumerable observations were made in regard to dosage, absorption of the radiations, and the nature of the response of the tissues to these radiations. Two main fields of investigation were open: (1) the physical dose, and (2) the tissue response. It was decided to concentrate on one tissue and, because of the advantages offered by the blood, it was arranged, as a preliminary investigation, to explore the changes induced in blood and bone marrow by X rays of known wave-length. Mr. W. V. Mayneord made the precise physical measurements of the radiation. The tissue response was measured by Dr. A. Piney, who observed the hæmatological and histological changes in a number of animals subjected to measured doses of X rays. The direction of the experimental work was suggested by the clinical observations made in a case of myelogenous leukæmia where apparently a progressive action on the blood was induced by measured doses of radiations, and where after cessation of treatment, changes, quantitative and qualitative, continued for several months until a minimum count was reached. The animal experiments establish that radiations initiate a change which is progressive, and which continues after the cessation of treatment, and independently of subsequent procedures. The conclusions are to some extent analogous to those made by Dr. A. Leitch on the production of cancer in animals by repeated applications of tar products; when the tar had been applied frequently and for a certain length of time and the irritant was then removed, carcinomata made their appearance at a later date. Dr. Piney found the effects of divided doses to be more intense and more prolonged than those of a single dose, whilst also having a rather different qualitative result—namely, the former cause no alteration in the monocyte count.

Massive Collapse of the Lung.

Dr. L. R. SANTE (St. Louis, Mo.) and Dr. D. R. BOWEN (Philadelphia) both read papers on this peculiar condition in which one or more lobes of the lung, without apparent cause, suddenly lose their air content and become atelectatic. First described by W. Pasteur in 1890, the condition is scantily mentioned in the literature until recent years. With the loss of air content the lung becomes smaller, drawing the chest wall down with it, the mediastinal structures inward and the diaphragm upward as it collapses. The resulting atelectatic lung produces as dense a consolidation as pneumonia. These rontgenographic findings are characteristic. Dr. Sante has observed under direct fluoroscopic vision that such a fully collapsed lung can be caused to reinflate in many instances, merely by rolling the patient back and forth on his unaffected side and causing him to cough, and he suggests this as a method of treatment. Dr. Bowen emphasised the recent rediscovery of atelectasis as a post-operative complication with precisely similar conditions to those recurring with foreign body or infectious disease.

Radium Treatment of Intrinsic Carcinoma of the Larynx.

Dr. N. S. FINZI and Mr. DOUGLAS HARMER (London) described their method as closely resembling that employed at Bayet's Clinic. The incision starts at the centre of the hyoid bone and extends outwards and downwards along the posterior border of the thyroid cartilage. The thyroid cartilage is exposed, the perichondrium stripped from it and the greater portion of the cartilage then resected, making a large window. A number of radium needles are then inserted under the cartilage, great care being taken not to penetrate into the growth or into the larynx. The needles are parallel and are placed vertically, each one touching the next. The greatest care is taken to prevent sepsis. The threads attached to the needles are buried beneath the muscles and the wound is completely closed until the needles are removed from 4½ to 8 days later. If the anterior commissure is involved the other side of the larynx is treated in the same way. About 7 mg. of radium element is used if one side only is treated and about 12 mg. if both sides are treated. The filter is 0·5 mm. of platinum and the time from 4½ to 8 days. In some cases a small dose of heavily filtered X rays has been given two or three days before the operation. The closed wound having been sealed by a collodion dressing, a low tracheotomy is performed to avoid trouble from swelling of the glottis, which may result from the radium treatment; this tracheotomy is usually kept open for about six weeks. Fifteen cases have been treated with the following result:—

(1) In eight of these the growth was confined to one vocal cord and did not involve either the anterior commissure or the arytenoid cartilage. In six the growths entirely disappeared and the patients have remained well for periods of from one to three years. Gramophone records will be used to show the superiority of the results as regards function over those obtained by laryngo-fissure. In most of them the vocal cords have recovered to such an extent that it is impossible to detect on which side the growths were situated. In one case the growth diminished in size, but a stenosis of the glottis resulted and the patient died suddenly eight months later of unknown cause. In the eighth case no real improvement resulted from the treatment.

(2) Five cases were advanced, the disease having crossed the middle line in front and involved the other vocal cord, so that nothing except some form of laryngectomy was available as a surgical procedure. One has remained well for four years; his vocal cords are freely movable and appear normal, but the voice result is not as good as would be expected (gramophone record). In one case the disease in the larynx entirely disappeared, but the patient died later from a recurrence, which occurred in the tracheotomy wound a year after the treatment. Of the other three cases, one died during the operation, in one no improvement was noticed, and in one there was improvement, but later recurrence.

(3) Two inoperable cases in which the disease had extended into the larynx or through the laryngeal cartilages into the neck with enlargement of the cervical glands. In one the growth disappeared and the glands were removed by operation; the larynx remained healthy for two and a half years, but there is now a thickening of the vocal cord, probably due to a recurrence. In the other there was very great improvement, but the patient died after 15 months, probably from mediastinal metastases.

It is claimed that in operable cases the after-results as regards function are superior to surgical operation, and, if they prove to be permanent, will probably replace it. In advanced cases there seems no doubt, they say, that radium should always be tried before laryngectomy.

X Ray Therapy of Exophthalmic Goitre.

Dr. G. FORSSELL and Dr. O. SANDSTRÖM (Stockholm) gave a survey of experiences at Radiumhemmet of the X ray treatment during the period 1918–25 of 80 cases of typical morbus basedowii. In 57 cases the treatment was completed and the results controlled by re-examination of the patients. Of these 57 cases 30 (52·6 per cent.) are now quite well and able to work; 13 (22·8 per cent.) are much improved and able to work, but still have certain symptoms; 75·4 per cent., therefore, have been rendered able to work; 5 cases (8·8 per cent.) are improved, but n quite able to work, and as many (5) are unimprov or worse; there are 3 (5·3 per cent.) recurrences aft recovery or considerable improvement having last for some time; there has been one death. Appro mately one-fourth of the number of cases have be of severe nature, the rest of medium severity. T risk of rontgen treatment in expert hands is sligh Yet there is a certain risk of producing hypothyroidis particularly in case of the nutrition of the thyro being reduced by some operative interference precedi or following the X ray treatment.

Dr. A. SOILAND, Dr. W. E. COSTOLOW, and I O. N. MELAND (Los Angeles) gave a critical survey radiation therapy in exophthalmic goitre, as reveal by a questionnaire, and show that of 5400 cases treat 73 per cent. were cured, 16 per cent. improved, a 11 per cent. unimproved. Failures to respond to t treatment are attributed to poor selection of cases the part of the physician, lack of coöperation on t part of the patient, and lack of radio-sensitivity of t goitre. Whether or not this last cause is corre cannot be definitely decided at present, as improveme in technique may eliminate it. This analysis giv figures which are comparable to those obtained surgery, with the added advantage of no mortali due to the treatment itself.

X Ray Treatment of Multiple Sclerosis.

Stimulated by the published successes of Marines (1910) and Duhain (1911), Dr. A. Romanowa-Lesko and Dr. K. W. Ipatow (Leningrad) began the tre ment of *sclérose en plaques* by X rays in 1922, a reported good results in two cases at the Psych Neurological Society of Leningrad in 1924, and in total of 30 cases at the Physiotherapeutic Society Leningrad in 1927. Their cases now number 40, which only 28 have been observed for more than year; the remaining 12 were lost sight of after so improvement had been achieved. Treatment administered in seven sittings; at intervals 1–2 days the skull is irradiated three times, the ne once, the chest twice, and the sacrum once. T series is given ten times in the year, the whole cou being repeated after an interval of 6 to 12 mont Of the 28 patients, 22 showed more or less defin improvement up to clinical cure, including impro ment of gait and speech, disappearance of trem return of abdominal reflexes, and so forth. No c was completely unsuccessful, but six were o slightly bettered. Improvement may only be appar after several months or even years. The auth employed hard rays filtered through 4 mm. aluminium, and a dose not exceeding 25 per ce HED measured on the skin.

New Method of Treating Asthma by Radiation.

While working on a special technique for treat cancer by radiation at the London Hospital, Dr. S. SCOTT noticed that the method had a beneficial eff on asthmatical patients. A number of cases of asth of all types have now been treated; in really bad ca the results are often spectacular. When bronch is predominant, while the attacks of asthma may relieved, the bronchitis itself is but little affect Certain observations suggest some metabolic influe on the ductless glands—e.g., (1) beneficial results be obtained by radiation of the abdomen on (2) increase in body weight is in many cases rema able; (3) there is a general feeling of well-be experienced by most patients. The method require large radiation field and small dosage. The fi includes the whole trunk, the abdomen being important area. The tubes are centred over epigastrium and over a corresponding point posterio The voltage should not be above 170,000, a filter 3 mm. aluminium being used. Treatment is gi twice weekly in bad cases and once weekly in aver cases, four to six being the course. No blood chan occur and only slight nausea in a few patients. Scott reported on 130 cases so treated, and sugges

hat the same technique might prove of value is whooping-cough.

Treatment by Irradiated Oils.

At the instigation of Prof. S. A. Brustein, Dr. Th. Rothstein (Leningrad) began three years ago to employ external treatment of painful affections by means of compresses of irradiated oil. The technique consists in exposing the fresh oil, whether obtained from the sunflower, peach, nut, or cod liver, to 500, 1000, or 1500 ultra-violet units measured on the Falkindson photo-quantimeter. The 176 cases treated included polyarthritis 71, neuralgia 92, the most conspicuous result being in every case a reduction of painfulness and a parallel diminution of local heat. The compresses seem to the author to have their use in every case where direct ultra-violet treatment is used, with the added advantage of portability. The activity of the irradiated oils lasts at least 15 months, during which time the oils retain definite physical and chemical changes in viscosity, absorption spectrum, and iodine number.

MEDICINE AND THE LAW.

Chemist's Duty under Dangerous Drugs Legislation: Conviction Quashed.

UNDER the Dangerous Drugs Act and Regulations a chemist must not dispense a prescription containing certain drugs unless (*a*) he is acquainted with the prescriber's signature and has no reason to doubt the genuineness of the prescription, or (*b*) he has taken reasonably sufficient steps to satisfy himself that the prescription is genuine. If he dispenses prescriptions otherwise than in accordance with the Regulations, he commits an offence against the Act. For an offence of this nature Henry Clarence Thompson, a chemist, of West Derby-road, Liverpool, was convicted last June by the Liverpool Stipendiary Magistrate, and was fined £40 with £5 5*s*. costs. The charge was that of unlawfully dispensing a prescription for grs. 20 morphia sulphate to William Arthur Young without having taken reasonably sufficient steps to satisfy himself that the prescription was genuine. Against his conviction Mr. Thompson has now successfully appealed. It appeared from statements made during the proceedings that Young had posed as a doctor in Liverpool without possessing the requisite qualifications, that he had attended patients and had even certified a mental case. Young was convicted of wilfully and falsely pretending to be a doctor and also of obtaining certain quantities of morphia sulphate from two chemists; he was sentenced to imprisonment, which he is at present serving. It was stated that he had practised as a doctor in Canada but had got into trouble, and lost his qualifications and had been deported. The prosecution of Mr. Thompson was obviously a sequel to the prosecution of Young. The most important evidence called on Mr. Thompson's behalf was that of Dr. W. R. L. Waters, of Tue Brook, who had met Young. Young told Dr. Waters that he was a Canadian mental specialist who wished to set up practice in Liverpool. "I did not look him up in the Register," said Dr. Waters; "he was a convincing person and had a good knowledge of mental cases; he impressed me as a man of ability, and I was satisfied that he was a medical man; I allowed him to see one of my patients with me, and he wrote out a detailed history of the case—a mental one." In answer to the Recorder (Mr. Hemmerde, K.C.), Dr. Waters agreed that the more a chemist had examined Young, the more he would have been satisfied that Young was a doctor; he also said that he would not have hesitated to let Young look after his patients at a week-end if he had been going away. The Recorder said that if there was nothing to make Dr. Waters suspicious, there was nothing to make Mr. Thompson suspicious. The latter's appeal was allowed with costs.

One medical practitioner meeting another occasionally in the course of professional routine does not hold him at arm's length till he has obtained authentic evidence of his identity, qualifications, and registration. Similarly a chemist, who gradually becomes acquainted with the signatures of doctors who practise in his neighbourhood, can hardly be expected to go through a similar process when presented with a prescription over a signature with which he is unfamiliar. Is it to be deemed compulsory for a chemist to keep on his premises a copy of the latest medical list? If he does so, he may still be deceived by a forged signature, or conceivably the owner of the signature may have been deprived of his qualifications since the list was published. Nevertheless, the law requires that such reasonably sufficient steps be taken by the chemist as will satisfy him of the genuineness of the prescription; he must certainly not refrain from following up any point which arouses his suspicion. With regard to Dr. Waters's answers to the Recorder, it is doubtless unnecessary to repeat the warnings which appear in "The Conduct of Medical Practice." A practitioner who enters into partnership, or who engages the services of an assistant, must in every case verify the fact of registration. Dr. Waters would no doubt have taken this step before entrusting any of his patients, for however short a time, to Young.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Research.

Sir Robert Philip's report, as curator of the laboratory of the Royal College of Physicians of Edinburgh, shows that the 24 investigators there have been doing good work on many different subjects. The use of taurine in tuberculosis has been further studied, and its influence on the disease has been found to be comparatively slight. The curator, with Prof. T. J. Mackie, has been doing research bearing on the standardisation of tuberculin; the superintendent (Lieut.-Colonel A. G. McKendrick) and Dr. W. O. Kermack have been carrying on their work on the mathematical theory of contagious epidemics, and Colonel McKendrick has also published a statistical examination of antirabic treatment in India. He has further collaborated with Dr. Kermack and Dr. Eric Ponder in their research on the sedimentation of red blood cells, whilst Dr. Kermack has, with various collaborators, investigated the chemistry of harmine and other alkaloids, the rôle of dihydroxyacetone in carbohydrate metabolism, and the physical properties of Wassermann antigens. Mr. C. I. B. Voge has continued his studies of the reactions of syphilitic and normal sera; Dr. C. G. Lambie and Dr. F. A. Redhead have made some interesting observations on the influence of pituitrin on the metabolism of glucose and dihydroxyacetone; Dr. David Orr has investigated the changes to be found in the nervous system of animals receiving intravenous injections of bacterial emulsions, and Dr. Donald Stewart has carried to a further stage his work on the chemistry and cytology of the cerebro-spinal fluid in children. Lieut.-Colonel W. F. Harvey, a newcomer to the laboratory, is examining Gram's method of staining unicellular organisms, and has found efficient substitutes for the alcohol, aniline oil or phenol constituents of the dye. He is also studying the parenteral introduction of foreign nerve material into rats. Other subjects being dealt with are the conditions which favour heat-stroke, the infection of children by pulmonary diseases, the pathology of deaf mutism, the histopathology of the skin, the types of tubercle bacilli found in surgical lesions, and the icterus index of serum in cases of jaundice.

Status of the Sanitary Inspector.

At the annual conference of the Sanitary Inspectors Association, held at Dunfermline, Dr. Frederick Dittmar, Chief Medical Officer of the Scottish Board

of Health, pointed out that the days were gone when it was believed that a policeman or a plumber should occupy the position of sanitary inspector. Generally speaking, the sanitary inspector nowadays had to know something about buildings, building construction, meat inspection, and dairy work, so that he must be a man of fairly wide training. He should have a first-class school training, and ideally should occupy some position similar to that of the articled pupil in the engineering trade, who first had his theoretical training, and then had to go through the shops. Something in that line would have to be marked out for the sanitary inspector of the future, and Dr. Dittmar thought it by no means impracticable. The status of the sanitary inspector might then take care of itself.

Factory Work and Welfare.

The report of the Chief Inspector of Factories and Workshops shows that there were over 18,000 accidents in Scotland last year, of which 145 were fatal. The deaths of two men who had for many years been employed in the manufacture of sheep dip present puzzling features.

The first man, who had been engaged in the manufacture of dip for over 30 years, died from chronic arsenical poisoning, bronchitis, and emphysema. The senior medical inspector (Dr. J. C. Bridge) remarks that in this case no lesion of the skin—a characteristic effect of arsenical poisoning—was observed, and as no autopsy was held, the association of arsenic with the cause of death remained obscure.

Inquiry was made into a somewhat similar case affecting a man, aged 51, who had been employed for 29 years also in a sheep dip works, although since 1923 he had been removed from contact with arsenic. Dr. Bridge states that "on three separate occasions growths had been removed from the skin, and in this case the post-mortem examination revealed the presence of chronic bronchitis, which might have been due to the exposure to arsenic dust, but this was not clearly established. A full investigation of cases such as these is of undoubted value."

A firm engaged in the manufacture of sheep dip has installed baths, and has made the taking of them a condition of employment of all those in contact with arsenical compound. Although there was, it is stated, a little difficulty at the outset, this was easily overcome, and subsequently these baths were made available for other employees, male and female.

Continued progress in improvement of welfare conditions is reported. A large printing and publishing firm in Lanarkshire has taken advantage of the decision to construct an up-to-date factory on model lines to launch an ambitious and comprehensive scheme of welfare work. Embodied in the design of the factory itself is every modern improvement that makes for efficiency and general welfare. The site has been chosen in the country, but by reason of excellent and cheap travelling facilities, the city centre is not far distant. The kitchen is entirely electrical, and meals are to be provided for the workers at prices scarcely above cost, whilst, for those who prefer to bring their own food, specially designed warming cabinets are provided. The lavatories are described by the works manager as probably superior to those in the best hotels of the country, and a separate self-locking lavatory has been allotted to each group of 20 workers, every worker being provided with a key.

V.A.D. Road Services.

At the Voluntary Aid Detachment gathering at Aboyne, the proposal was discussed to utilise the services of V.A.D. nurses for first-aid and other work in connexion with road accidents. Dr. J. C. M. Matheson, of Laurencekirk, said that headquarters had expressed their approval of the scheme, and he was hopeful of seeing all arrangements in Kincardineshire completed shortly. War was a very remote possibility, and a vigorous effort should be made to deflect the training and experience of many capable nurses into the service indicated.

The movement is also receiving support in Aberdeen, and is expected to spread to other counties in Scotland.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Censorship of Publications.

IMMEDIATELY before the adjournment of the D the first reading was taken of the Censorship Publications Bill, 1928, a measure designed to prohi the sale and distribution of unwholesome literatu The text of the Bill has, however, been issued on within the past few days. Apart from its pure moral and social aspects the Bill has special intere for the medical profession. It is proposed to set up board of five censors, on the report of four of whom t Minister of Justice may issue an order prohibiting t sale or distribution of a book regarded by them indecent or obscene, or tending to inculcate princip contrary to public morality, or of such character th it tends to be injurious or detrimental to or subversi of public morality. Similar action may be taken regard to a periodical, recent issues of which may adjudged to have offended. Disobedience to an ord may be punished by fine or imprisonment, or both, an in any case, forfeiture of the book or periodic Special sections limit the publication of certain matte in relation to divorce proceedings or other proceedin dealing with the marital relation, and legal proceedin in general. The Bill, however, goes much further th this. It prohibits, otherwise than in accordance wi a permit granted by the Minister, the publicatio selling, or keeping for sale, and the distribution any book or periodical which advocates or mig reasonably be supposed to advocate the unnatu prevention of conception or procurement of aborti or miscarriage, or any method, treatment, or applian to be used for the purpose of such prevention procurement. Moreover, the printing of adverti ments which relate or refer to any disease affecting t generative organs of either sex, or to any compla or infirmity arising from or relating to sexual int course, or to the prevention or removal of irregularit in menstruation, and certain other matters, is brou under the Indecent Advertisements Act of 18 Another section deals with the exposure of indec pictures.

Much of the proposed legislation deserves co mendation. The prohibition of the advertisement quack cures for venereal diseases and of "cures female irregularities" is long overdue. Few v quarrel, except perhaps on academic grounds, with limitation of the reporting of divorce and similar le cases—a reform already adopted in England. But virtual branding of propaganda in favour of bi control as indecent will take many aback. The eth of birth control are a subject of lively controversy the moment, and the ethical question can hardly settled by a legislative enactment. In regard to ot matters there is a grave danger that if a board puritanical or uncultured censors should be appoint both literature and art would speedily feel themsel cramped.

Royal Institute of Public Health.

The annual congress of the Royal Institute Public Health was opened in Dublin last Tues evening by a reception given by the Minister of L Government and Public Health, who is President the Congress. On the following and subsequent d the several sections met for discussion.

A LANCASHIRE REST HOME.—The Directors British Insulated Cables, Ltd., of Prescot, Lancashire, bought Upper Downing, Flintshire, for a rest home as of an after-care scheme for sickness and accident cases an their employees. The cost of maintenance will be defr by the Hospital Fund Committee of the employees. U Downing, which by now has been opened, was buil 1589, but was remodelled in the Georgian period. stands close to Downing Hall, long the home of Tho Pennant, traveller and naturalist.

GENERAL MEDICAL COUNCIL.

EXECUTIVE COMMITTEE.

T a meeting of the Committee, held on July 23rd, Norman Walker was appointed a member of the tal Board in the place of the late Sir James sdon.

Restorations to the Register under Section 14.

he following names, erased owing to failure to y to the Registrar's inquiry, were restored to the ical Register :—

omas Allen, Robert J. Baylor, Chas. Wm. Dixon, Douglas, John Dwyer, Mervyn Eager, Lennard Game, ld W. Hodgson, M.C., Elizabeth S. Martin, Vivian hew Matthews, Evelyn Arthur Rich.

Direct Representative.

letter was read from Sir Robert Bolam, resigning membership of the Council as a Direct Repre- ative on his appointment as Representative of University of Durham. The vacancy thus caused be filled by an election to be held before the ember Session, at the same time as the election Direct Representative to fill the vacancy caused he death of Dr. Macdonald.

Union of South Africa Medical Act.

copy of this Act, which also relates to the man- d territory of South-West Africa, was received the Dominions Office. This Act provides that Governor-General, after considering any recom- dation by the Council, may prescribe by regulation diplomas, &c., which entitle to registration vided that they entitle the holder to practise in country in which the body granting it is situated, there is reciprocity between the Union and the ntry, and that the standard is not lower than that uired in the Union. The Governor-General may e regulations for the registration of medical and al students. Any unregistered person who tises as a medical practitioner, or performs any specially pertaining to the calling of a medical titioner, or pretends to be a medical practitioner, able to a fine not exceeding £100. There are lar penalties provided in regard to dentistry. use of the British Pharmacopœia is enjoined. registered person may make extortionate charges services rendered, and if the fee exceeds that lly charged he must, before rendering the service, rm the person concerned of the fee which it is nded to charge. Persons mentally disabled may uspended from carrying on their profession.

North Australia.

formation was received from the Dominions e relating to the practice of medicine and surgery he Territory of North Australia. It appears the South Australia Acts of 1844, 1880, and 1889 in force in 1910 when the Northern Territory e under the authority of the Commonwealth, still hold. The Act of 1844 states that no one l be deemed a legally qualified medical prac- ner unless he shall have proved to the satisfaction he Medical Board that he held a satisfactory ification. In the Act of 1880 this was repealed, it was enacted that no one was to be deemed edical practitioner unless he possessed one of the lifications contained in the Schedule. The dule, however, was not supplied. In the Act 89 the Schedule was repealed, and a new Schedule appended, which included any qualification tling to registration in the United Kingdom, a ee of any University in Australasia legally orised to grant it, and a degree or diploma ted by any body in a British Colony or Possession, ny foreign University which in the opinion of the ical Board was equal to a qualification entitling gistration in the United Kingdom.

Indian Qualifications.

A communication from the India Office supported a request by the University of Bombay for the extension of the recognition of its M.B., B.S. degree of the University for a further period of three years. The question of appointing a Commissioner of Qualifications and Standards pending the creation of a Medical Council for India has, it was stated, been referred by the Government of India to the local Governments for their consideration. Their replies have not yet been received. It was resolved to recognise for one year the medical degrees of Bombay, Calcutta, Madras, and Punjab Universities, until July 31st, 1929, subject to the receipt (before July 1st, 1929) by the Council of a satisfactory report by an inspector or inspectors appointed by the Government of India and approved by the Council on a Final Examination held in the academic year, 1928–29.

Training of Midwives.

In view of the appointment by the Ministry of Health of a Committee to deal with the functions and training of midwives, it was resolved to ask Sir Donald MacAlister to attend before the Committee on Oct. 24th to explain the general views of the Council, and to introduce Mr. Eason, Sir Leslie Mackenzie, and Mr. Johnston, who should be requested to give evidence relating to the three divisions of the Kingdom.

Definition of Abortion.

At a previous meeting of the Committee, doubt was expressed as to whether the definition of "abortion" in the amended Rules of the Central Midwives Board was sufficiently clear or accurate. The Ministry of Health stated that the definition had been altered to read as follows :—

"The passage of the contents of the uterus before the fœtus is viable—that is, of an age at which it may be reasonably expected to survive. (Note.—For practical purposes a fœtus is not viable before the twenty-eighth week of pregnancy.)"

Obituary.

GEORGE EDWARD WHERRY, M.CHIR. CAMB., F.R.C.S.ENG.

WE regret to announce the death of the well-known Cambridge surgeon, Mr. Wherry, which occurred on August 12th, in the seventy-seventh year of his age. The whole of his professional life was spent in the University city, and the number of Cambridge medical graduates who have regarded him as a friend, both during their undergraduate days and later, must be enormous.

George Edward Wherry was born at Bourne, in Lincolnshire, received his early education at the local grammar school, and, entering the medical school of St. Thomas's Hospital in 1870, obtained his first diploma, M.R.C.S.Eng., at the age of 21. From St. Thomas's Hospital he proceeded to Cambridge as house surgeon at Addenbrooke's Hospital, being admitted at the same time to Downing College as an undergraduate of the University. He held the resident post at Addenbrooke's for four years, and during that time graduated in arts at the University. He took the M.B., B.Ch. degree in 1878, and in the following year he proceeded to that of M.C. In the same year he took the Fellowship of the Royal College of Surgeons of England, and was appointed surgeon to Addenbrooke's Hospital.

In 1883 Sir George Humphry, to whom Wherry owed his original connexion with Addenbrooke's Hospital, resigned the Professorship of Anatomy to take the new and unpaid Professorship of Surgery, and in the same year a University Lectureship in Surgery was established, when Wherry was appointed to the post and held it until its suppression nearly thirty years later. He was never actually Professor

of Surgery. This post was not filled up for seven years after Humphry's death in 1896, when in 1903 Howard Marsh, while still connected with St. Bartholomew's Hospital, was invited to the chair. Four years later Marsh became Master of Downing College, and held the post of Professor until his death, since which it has not been filled up. But if Wherry was never professor in name, no professor could possibly have been more closely associated with the science of surgery as a University subject or more keen for its development than he was. He lectured assiduously, held clinical classes in the wards, acted frequently as an examiner, and supervised during the ten years immediately following the death of Howard Marsh the whole surgical faculty of the University.

Outside his professional work Wherry was well-known to a large circle as an Alpine climber, an antiquarian, and a man of diverse and highly cultivated literary tastes. He married in 1881 Albinia Lucy, daughter of Robert Needham Cust, of the Bengal Civil Service, by whom he had one daughter, who became the wife of Major R. W. Oldfield, Military Attaché to the Legation at Prague.

CHRISTOPHER CHILDS, M.D.Oxf., D.P.H.Camb.

THE death took place on Monday, August 6th, at his residence, Rock House, West Looe, Cornwall, of Dr. Christopher Childs, a well-known pioneer in sanitation and epidemiology. He had reached the age of 81.

Christopher Childs was born at Liskeard, and received his early education at Uppingham School, where he was distinguished alike in work and play, being an exhibitioner, a great runner, and the captain of the football fifteen. From Uppingham he proceeded to Merton College, Oxford, and graduated with a first class in the Natural Science Tripos. Deciding to enter the medical profession, and having won the Radcliffe Trust Special Prize, he completed his clinical course at St. George's Hospital, took the diplomas of the English Colleges, and became house physician to the institution. London practice, however, had no great attraction for him, and for a short time he returned to his old school as science master, when he was able to assist the famous head, Edward Thring, during a dramatic transference of the school from Rutlandshire to Wales, following upon an outbreak of typhoid fever. In 1882 he decided to commence general practice at Weymouth, and for some 12 years he conducted a large practice in that town and neighbourhood, but again he felt that he had not found the career that most appealed to him. At this time the problems of public health and sanitation became more obviously attractive to the medical man with special scientific equipment. In 1895 Childs acquired the diploma of D.P.H. at Cambridge, and left Weymouth for Manchester-square to practise as a sanitary expert. He was accepted quickly as an authority, wrote ably upon epidemiological subjects, and in particular made some comparative studies of typhoid fever epidemics which well represented the knowledge of the time. He lectured on bacteriology and hygiene at University College, London, and examined in those subjects for the English Conjoint Board.

He retired, however, while still in middle age, and removed to Looe, where he passed the last twenty-four years of his life devoting himself to the public welfare of the town, and, indeed, of his native county, being particularly interested in the fortunes of the Cornish fishing industry and the promotion of ambulance work. He was a Knight of Grace of the Order of St. John of Jerusalem.

One who had been his pupil at Uppingham writes: "Childs was a man whom those of his juniors who came into contact with him will always remember as an old friend. Uppingham, during his brief term of office as a science master, was mainly a classical school, and it is doubtful if Childs would have occupied a position of real authority among us l it not been for his personal kindliness and his rec on the playing field as athletic champion and capt of football. But the few of us who worked un him in his simply equipped laboratory gained insight into the beginnings of scientific work wh made the later approach to serious study far eas for us."

Dr. Childs married Miss Anne MacRea, of Weymou who predeceased him, and by whom he had one s

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. S. G. Rainsford to be Surg. Lt.-Comdr.

The following appts. are notified: Surg. Rear-Adm H. C. Whiteside is placed on books of *President* w attending conference of Association of Military Surge of the United States. Surg. Comdrs: F. C. Wright *Vindictive;* A. C. Anderson to *Argus;* J. Bourdas to *Vic* for R.N. Barracks, Portsmouth; and H. M. Langdale *Vernon.* Surg. Lts. E. T. S. Rudd to *Pembroke* for R Infirmary, Chatham; T. Rees to *Hood;* A. S. Nico *Impregnable;* D. R. Campbell, L. J. Corbett, and S Savage to *Broke* (on recommg.). Surg. Lt.-Comdr. B. J. Geekie to *Malabar* for R.N. Hospl., Bermuda.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. W. C. Croly retires on retd. pay.

Maj. C. Clarke, Reg. Army Res. of Off., relinquishes appt. and resumes the rank of Lt.-Col.

The undermentioned Lts. (on prob.) are confirmed their rank: F. McL. Richardson, J. W. Eames, and S. R Mackay.

TERRITORIAL ARMY.

Capt. E. White (late R.A.M.C.) to be Lt. and relinqui the rank of Capt.

W. F. Mulvey to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. A. Greenwood, having attained the age li relinquishes his commn. and retains his rank.

ROYAL AIR FORCE.

Flight Lt. H. W. Corner is granted a permanent commis in this rank.

Capt. W. R. Wotton (Army Dental Corps) is grante temporary commission as a Flight Lt. (Dental) on att ment to the R.A.F.

Flight Lt. (Hon. Sqdn. Ldr.) J. W. H. Steil relinqui his temporary commission on completion of service an permitted to retain his rank.

INDIAN MEDICAL SERVICE.

C. L. Noble to be Lt.

Sunderdas Tulsidas Sodah to be Temp. Lt.

ROYAL ARMY MEDICAL COLLEGE.

The following prizes were awarded at the conclusio the summer course for Lieutenants on probation, R.A.M and I.M.S., at the Royal Army Medical College, Grosve road, London, S.W.: Herbert prize (about £20): Hig aggregate marks, Lt. F. McL. Richardson, R.A.M First Montefiore prize (£20 and bronze medal): Hig marks in military surgery, Lt. A. McMillan, R.A.M Second Montefiore prize (£7): Second highest mark military surgery, Lt. S. S. Bhatnagar, I.M.S. Pa Memorial (medal and £5): Highest marks in hygiene, F. McL. Richardson, R.A.M.C. Ranald Martin (medal £5): Highest marks in tropical medicine, Lt. F. M Richardson, R.A.M.C. Tulloch Memorial (silver me Highest marks in pathology by an R.A.M.C. officer, G. T. L. Archer. Fayrer Memorial (bronze med Highest marks in pathology by an I.M.S. officer, Lt. C. Cropper. De Chaumont prize: Second high st mark hygiene, Lt. S. R. M. Mackay, R.A.M.C.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Changes in Pensions Administration.

EFORE the prorogation of Parliament, on Friday, ıst 3rd, some important questions of policy in the sment of post-war disability pensions and the medical ment of pensioners came up.

ı the motion for the third reading of the Consolidated l (Appropriation) Bill,

r ROBERT HUTCHISON said, in view of the important ment made by the Minister of Pensions recently, he that opportunity of raising some important points. e was one point in the statement on which he would some elucidation—namely, the question of allowances reatment. They had now got so far away from the that many of those who were still suffering from ads, from the affects of gas, and from nervous disability l be considered chronic, and their condition was on a different plane from what it was ten years ago. He ested that there were a great many cases which would uch better cared for in regular institutions where their ition might be ameliorated. They knew of cases where le had been sent for treatment again and again by cal boards, and the nervous exhaustion of the individuals had to undergo that treatment, and in some cases ations, was pitiful. Some attention ought to be given is very serious matter. His next point was as to the inuance of re-examination before medical boards for sessment of pensions in quite a small number of cases. argument was used that after a final assessment and the ıg of a final pension there were cases that got worse; statistics would prove that almost 95 per cent. of the s that had been given final awards did not come up for sessment. It seemed to him that the time had arrived h the Ministry should deal generously with the remaining s, and give them a final pension, even though it might o the detriment of the State. The amount of money lved must be small compared with the total expenditure. Government might also consider a definite proposal for ng down the Ministry of Pensions step by step over a od of a few years. Large blocks of people could be ı a statutory right to their pensions which would be through the Post Office, and the cases which fell for inual attention might be handed over to institutions, o the care of the medical authorities through the stry of Health. In that way money could be saved direction in which, at present, there was extravagance dering the work which had to be done. The statement e by the Minister as to the stabilisation of pensions had ened the hearts of many, but the more they could down the Ministry the better it would be for all erned.

r. F. ROBERTS said that the House agreed that the rnment had taken the right and proper course in the lisation of war pensions. He would offer resistance to R. Hutchison's proposal with regard to the closing ı of the Ministry of Pensions. They recognised that must be some contraction of the work, but the more looked around the more they understood how big the tion was that confronted them, and how important it to have a Minister in the House of Commons who l be questioned in regard to the problems affecting ervice men. It was essential to maintain this Depart-, with its voluntary workers and officers throughout country, in order to keep in operation that human ı which was more necessary in connexion with ioners than perhaps any other department of our social If the Minister of Pensions and the Government were prepared to accept the view that there should be no limit, and that if a man was suffering from a war ility, he should thereby be entitled to pension, then he Roberts) would ask the right hon. gentleman to what at he was prepared to go in meeting the needs of those asthenic and tuberculous cases which from time to time such a source of great anxiety. He would also like to he Minister whether it was his intention to provide special ment for border-line cases, in regard to which it was tful whether the policy applied was that which Parlia- and the country desired.

The Future of the Ministry of Pensions.

eut.-Colonel FREMANTLE said he would like to speak the point of view of the medical service and medical nistration in the Ministry of Pensions. It was some- forgotten that the Ministry of Pensions was a most ntial part of the health services of the nation, although it was divorced from the general health services. They were all immense admirers of the Minister of Pensions and the work of his staff, but the stoutest defender of the Ministry as a separate entity must admit that it would come to an end one of these days, and it was right that they should envisage the future and try and consider to what extent it was likely to be changed. After they had stabilised the greatest number of pensions this largely became a medical question. From the medical point of view one obviously supposed that before the general body of pensioners had passed into another world rather than have the whole system of treatment of the few that remained die of inanition, the duties of the Department would have to be passed over to some other Department, and the question was how soon that should take place. It was quite true that that was not a question of immediate politics; but it was obvious that sooner or later the responsibility for the institutions and the personnel would have to be transferred. The natural body to complete and wind up the service would seem to be the Ministry of Health, but that would associate itself in their minds with the poor-law guardians, and there had always been a great and natural reluctance to imagine the possibility of in any way fusing this service with the service of the poor-law guardians. The proposal of the Government in the big Bill foreshadowed for next session was, however, to transfer the whole system of the poor-law into the hands of larger authorities—the county councils and the county borough councils—and he thought they would there have a new envisagement of institutional treatment and public health. They would have larger authorities possessing an enlarged service of institutions with a very large field of employment; because, if the new Bill passed substantially in the form in which it was proposed, they would be taking over the whole of the services of that kind, whether they were in the hands of the guardians or those of the district sanitary authorities. He was not going to say straight away that that in itself would qualify them to take over, or operate, the services of the Ministry of Pensions, but it was obvious that it gave them a prima facie reason for believing that they would be the body for that purpose. All that, however, was in the future, and they would, first of all, have to see how this reform worked out. When the counties had produced their schemes and got to work for a year or two, it would be possible to judge whether they would be able to relieve and help the Ministry of Pensions in this work. The Minister would have to consider what was to be the future of his institution and his personnel. The personnel must be a gradually diminishing one, but it would be a very difficult thing to know how to deal with it. There was a whole series of eminent medical men who had given themselves up to the Pensions service, who were chosen for work at the end of the war as the result, perhaps, of their war service, and it would be a difficult thing to turn those men out of the service and give them no future at all. In the same way with institutions; it would be a bad thing to see institutions contracting and becoming less efficient while they had to undertake big schemes for their fusion with all the geographical difficulties that would entail on pensioners and in other directions. Therefore, it was right that the Ministry should envisage the possibility of bit by bit gradually working in and coöperating with the Ministry of Health, and eventually the county and county borough councils, for the gradual fusion of the two services for which, in so far as pensions were concerned, the Ministry of Pensions would naturally retain its responsibility. Only at a later stage would the Minister transfer the institutions to the Ministry of Health.

They had to consider yet another side, and that was the future of the whole of these institutions with their personnel, and this service which had been built up by the present Minister of Pensions and his predecessors. They had developed a new medical science. This subject of the assessment of liability and the attributability of disease to war, with all its difficulties, had been developed by this service, and had become a fine art akin only to the medical service in connexion with insurance. It would be invaluable to the nation as a whole. The institutions with their specialist forms of treatment, as well as their general forms of treatment, had attained a very high professional position, and a high degree of skill and equipment. The great pity was that that should not be made available to the civil population in the future. If the personnel and the institutions were left gradually to slide down and down, though living an independent life, they would lose their standing and value in a large degree before they were transferred to the civil side. The Minister of Pensions should be considering in what way he could coöperate with the Ministry of Health and the other civil authorities in catering for some of the civil needs of the population, and in that way help to keep alive his institutions and maintain them at their highest possible pitch of fitness.

Dr. DRUMMOND SHIELS said he was unable to join in the mild congratulations which had been generally given to the

Minister, because he was thoroughly dissatisfied both with the policy and the spirit of the Ministry of Pensions. He agreed that it was very desirable that they should have had an intimation that week on the stabilisation of pensions, although in effect it only meant that after 1931 the present position of pensions was to continue. He did not criticise the present Minister specially, except that he thought he had been more accommodating to pressure from the Treasury than any other Pensions Minister. The Pensions Ministry had been under the domination of the Treasury ever since January, 1920. He could bring forward any number of cases which had gone through his hands where men had undoubtedly suffered in health very seriously because of the war but were receiving no pension, or only a miserable pension. Lieut.-Colonel Fremantle had spoken about the medical point of view. He (Dr. Shiels) was not particularly concerned at present about the future organisation of the Ministry. The medical point of view in which he was interested in connexion with the Ministry of Pensions was the way in which the Ministry turned down the opinions of medical men, not only panel doctors, many of whom were extremely and naturally indignant, but also well-known specialists, whose opinion was flouted by the Ministry of Pensions. He was not sure that it was by the medical men in the Ministry of Pensions. The medical men in the Ministry were not supreme. But they all knew of cases where a man was told that his case was one which made home treatment suitable; he did not require any hospital treatment, but his case could be dealt with by his panel doctor. He went to the panel doctor, and the panel doctor examined him and said that in his opinion the man required either hospital treatment or specialist treatment, and sent him back to the Ministry. Then the man was pushed backwards and forwards and was refused the treatment which the panel doctor thought was desirable. Even the opinions of medical specialists were set aside. He (Dr. Shiels) thought the Ministry of Pensions should give more heed to the opinions of conscientious medical men who knew the patients, and in many cases knew them before the war, and who understood the change that had taken place.

Mr. MONTAGUE said he did not altogether agree with Dr. Shiels in reference to the point raised by Lieut.-Colonel Fremantle, because he thought that Colonel Fremantle's reference to the use of an efficient State medical service for the civil population was a very big advance towards the point of view that the Labour Party held in regard to medicine and the nation as a whole.

The Minister's Reply.

After further debate,

Major TRYON, Minister of Pensions, said that as a result of the work of a committee presided over by Sir Godfrey Collins, the problem of artificial limbs for ex-Service men had been most satisfactorily settled. He believed that the limbs now supplied were probably the best supplied by any country which took part in the war. He had seen a suggestion that the 6000 men who had lost their reason would get nothing if it was not for the ex-Service Men's Welfare Society. That was a statement which no doubt enabled the Society to obtain funds from the charitable public, but it was absolutely untrue, because that Society under the law was not able to deal with a single one of the 6000 mentally afflicted men in the asylums; and so far from it being the case that the State had done nothing for them, the State had for many years past been spending about £3,000,000 a year on mental cases alone. The doctors of the Ministry were doing a wonderful work for these cases. He did not think the country generally realised how much the ex-Service men owed to the wonderful work which had been done for the sick and disabled by the medical staff of the Ministry. It was true, as Colonel Fremantle had said, that medical science had advanced, and he was glad to see that in a hospital which had hitherto been doing much work for the ex-Service men the great experience gained in connexion with the loss of limbs had been used to help railway men who had lost their limbs in civil employment. In that way they hoped to carry on the medical experience gained through these terrible sufferings, in order that the knowledge so obtained might be of assistance in civil life to other sufferers.

The Bill was read the third time.

SHEFFIELD PENNY-IN-THE-POUND SCHEME.—It is officially stated that this fund will this year be able to distribute £100,000 among the four Sheffield hospitals. Last year the amount so distributed was £88,809, out of a total of £116,816. The balance was expended upon the ambulance, convalescent, and other services. At the end of 1927 the joint debt of the Sheffield hospitals was £59,000 as against £111,000 twelve months earlier.

"Audi alteram partem."

THE HEART AND CIRCULATION IN BERI-BERI.

To the Editor of THE LANCET.

SIR,—In the St. Cyres lecture, published in your issue, Prof. Wenckebach has dealt with the prob of the beri-beri heart, and has supplied a most in esting and suggestive explanation of the difficulties with. At the same time he has introduced a new of the mechanics of the heart and circulatio connexion with the action of the right and ventricles. This new view may be correct, but a acceptance entails the dropping of well-establi beliefs some caution is required.

The leading features of the beri-beri heart w appear to be dilatation and weakening of the ventricle, weakening of the left ventricle, increa stasis in the liver and venæ cavæ, and a pulmo circulation completely free from any sign of st These phenomena taken by themselves would su a condition of congestive heart failure, but Wenckebach has accepted the statements of authorities on this disease that the chief lesion the right ventricle, and that the circulatory dist ances are due to its failure. He says that cli experience has taught him "that in cases of increa insufficiency of the whole heart the right hea doomed beforehand to suffer much more than the and even to suffer to the profit of the latter." can only be tested by the effect on the circulation cases of the beri-beri heart the pulmonary circul goes on unimpaired, so that one may assume an ciency of action and an absence of suffering as reg the right ventricle. On the other hand, congesti the liver and large veins, with a feeble apex beat a weak, rapid pulse, suggests that it is the left vent which is in difficulty. The teachings of cli experience as given above may be right or ma wrong, but they do not seem to find much suppo the clinical features of the beri-beri heart.

The great function of the right ventricle is to on the pulmonary circulation. In the beri-beri h the weakened and dilated right heart develops in petence of the tricuspid valve; Prof. Wencke says that "blood passes from the right heart backw into the veins and liver, and the arterial output o right ventricle is greatly reduced." Here we hav back-pressure theory in all its nakedness, but in of this failure of the right heart, "there is no lung s no râles, and no pulmonary œdema." In short, disabled and dilated right ventricle is carrying o normal function most efficiently, and at the same is doing extra work in pumping the blood back int venæ cavæ and liver until they are gorged with b But this is not all the trouble of the right vent "The right heart has to deal with the whole volu blood returning from the periphery to the h *the left heart not receiving more blood than the right is able to transmit.* Consequently the right heart the time struggling for life against an ever-increa overfilling and widening, but the left heart is sp a similar burden." But why this life and death str of the right heart? Is it so clear that it is the a of the right heart which has over-distended the cavæ and liver? No action or inaction of the ventricle can produce such stasis of the venæ and liver when at the same time an efficient pulmo circulation is being carried on. One can conceive the right heart may fail to carry on an efficient monary circulation, with some reflux through tricuspid valve, or that the right heart may carr the pulmonary circulation efficiently without reflux, but one cannot conceive that the right should be carrying on the pulmonary circul

ccessfully and at the same time be pumping the liver l of blood. The closing stages of the beri-beri heart e no less puzzling, for now, at long last, the left ıtricle comes into the picture. "At the last moment fore death the latter loses its systolic power, cumbs, and leaves the lungs with stagnating blood d signs of ante-mortem œdema." Surely these lmonary signs are to be traced to a failure in action the right and not of the left ventricle, and they ppen to be the first unequivocal signs of right-sided lure which the lecturer has described in connexion h the beri-beri heart.

Prof. Wenckebach seems to have accepted the statents of the authorities on beri-beri as to the special diac changes present, and on this basis he has built ıew theory of cardiac physics. He promulgates a w law of the heart as follows: "In equal and reasing feebleness of the whole heart muscle the ient suffers most and dies from the failure of the ht side of the heart only." The beri-beri heart may uire new views of the circulation and new laws of action of the two sides of the heart, but there is l something to be said for the old ones. In the i-beri heart the left ventricle is weakened and rate is increased. The signs of right-sided failure which so much stress has been laid might more ıvincingly be explained by failure of the left ıtricle. The engorgement of the liver and large ns, ascribed to the back pressure from the right heart, now usually ascribed to the diminished forward ssure of the left ventricle. It is the characteristic n of a failing left ventricle. The total absence in i-beri of signs of disturbance in the pulmonary culation—no stasis, no œdema, no dyspnœa—uld indicate a right ventricle working at its ease and ll within its powers. The arterial output of the ıtricle must be quite up to normal, and if at the ne time it is pumping blood into the liver, while its scle is seriously weakened by disease, we have indeed henomenon which requires some new law.

Prof. Wenckebach was an honoured guest of the yal College of Physicians at the recent Harveian brations, and saw the demonstration by Sir Thomas vis of Harvey's original experiments. Might I gest that he test the truth of his new views, in the nner of Harvey, by some physiological experiments show the circulatory correlation between the two es of the heart? It was not Harvey's theories, but experiments which carried conviction to the ptics of his time, and no doubt the same would ly to-day.

I am, Sir, yours faithfully,

ondon, August 12th, 1928. G. A. SUTHERLAND.

HERPES ZOSTER AND VARICELLA.

To the Editor of THE LANCET.

IR,—I read with interest the note on p. 264 of E LANCET, August 4th, and while reports of the elopment of the two maladies side by side are now frequent to be of much interest, yet I cannot ain from mentioning a small epidemic of chicken- I saw recently. Occurring as it did in an isolated nd district where there was little possibility of side infection the relationship between the illnesses s very definite.

n Jan. 6th last I was called to see a case of herpes er in a woman who had a definite history of previous ility and gastric disturbance. The rash had developed days before and was unilateral along the course of the t seventh intercostal nerve. On Jan. 12th I was called ee her son aged 25 who had a most profuse and typical cella with considerable constitutional disturbance, uding a sore throat and total suppression of urine for ours. On Jan. 13th a nephew aged 8 years, who had t with his aunt for several nights and had then returned is own home about a quarter of a mile away during the k prior to the development of her herpes, developed cella. He had not been near the house after my visit Jan. 6th. On Jan. 22nd the child's small brother and r and a playmate simultaneously developed varicella showed much less constitutional disturbance.

The cases caused considerable interest and alarm amongst the cottars, who could hardly believe in the origin of chicken-pox. A few years ago my principal had a case of an elderly lady visiting a sick child on her estate. The illness was found to be chicken-pox, and about a fortnight later the lady developed a very severe attack of herpes zoster.

I am, Sir, yours faithfully,

FLORA L. MACDONALD, M.B., Ch.B.,
Assistant General Practitioner.

Isle of Mull, August 11th, 1928.

POST-OPERATIVE MASSIVE COLLAPSE OF THE LUNGS.

To the Editor of THE LANCET.

SIR,—We read with great interest Dr. K. D. Wilkinson's letter in your issue of August 4th (p. 257). In our communication the term collapse is used exclusively in the sense that Pasteur originally intended it—namely, to indicate a complete apneumatosis of the affected lung, deflation being applied to the varying degrees of shrinkage that can occur without complete airlessness. We suspect that Dr. Wilkinson does not intend a similar distinction and this may account, in part, for his attitude towards our theories.

It is recognised that the assumption of the supine position in any circumstances is accompanied by a definite decrease in the vital capacity, or deflation of the lungs. It is our contention that following abdominal operations this is increased by a limitation of the respiratory movements which is partly reflex and partly voluntary in origin. This additional influence is most marked following upper abdominal operations, and for purely mechanical reasons it affects the lower more than the upper lobes, and these in males more than females, but the resulting deflation can never be more extreme than that of forced expiration, and apart from active compression there is only one method by which the lung can become completely airless, that is absorption of the alveolar air following obstruction of the bronchial tree.

The onset of post-operative massive collapse following the obstruction of a bronchus may be insidious, the physical signs when the block is complete being those which have been described as "dead lung." The sign of consolidation appearing only when the obstruction is removed without aeration of the alveolar tissue, but when a lobe which is already deflated becomes collapsed because of the diffuse obstruction of the bronchioles, the initial signs may suggest consolidation, followed later by those of "dead lung," because of the accumulation of secretions, and later still by those of consolidation when these secretions are removed. We think that examination of this hypothesis will explain many of the difficulties which Dr. Wilkinson raises. It is not at variance with a known physiological fact and it does not necessitate the assumption of anything which cannot be confirmed experimentally. We submit, however, that although Dr. Wilkinson's very ingenious theory might account for extreme deflation of the lung it could not account for the absolute airlessness which we regard as an essential of massive collapse.

We have had no personal experience of massive collapse occurring after gun-shot wounds of the chest and elsewhere, but feel that they can be explained by bronchial obstruction, and in this connexion we think that insufficient attention has been given to Curl's observation, that even non-pentrating wounds of the thorax are followed by bronchial hypersecretion which is often almost confined to the opposite lung, due in his opinion to a contrecoup mechanism such as occurs in cranial injuries. Given this hypersecretion and voluntary suppression of the expulsive efforts it is easy to see how bronchial obstruction may arise.

We agree as to the necessity of administering an efficient pre-operative and in some cases a post-operative dose of atropine, and suggest that the favourable reports which Mr. Hamilton Whiteford

gives in his letter may be partly explained by the favourable climatic conditions under which he works and the exclusion of morphia from the routine.

We are, Sir, yours faithfully,

CHARLES R. BOLAND.
J. E. SHERET.

Ancoats Hospital, Manchester, August 8th, 1928.

THE VACCINATION COMMITTEE'S REPORT.

To the Editor of THE LANCET.

SIR,—The report, of which you gave the chief features in your issue of August 4th (p. 233), is a curious document in that its inside bears so little relation to the terms of reference on its outside. We seem to learn from it:—

1. That a certain amount of standardisation of vaccine has been done, but that the relation between any particular vaccinal dose and the immunity conferred by it is unknown.

2. It is recommended that a trial be made of vaccination by one insertion as is done in Canada, instead of by four marks as is at present the law here. Three such vaccinations per person are advocated, the first in infancy, then at school-age, and again between 14 and 16 years of age.

3. It is suggested that vaccination might be performed more aseptically in infant welfare centres than in some homes, and that public vaccinators should inspect their patients twice instead of once.

4. It is stated that vaccination may have some causal responsibility for the encephalitis which occurs ten days after vaccination.

5. Vaccination at epidemic and non-epidemic periods are not considered separately, save that it is assumed, no proof being given, that the revaccinated and those vaccinated in infancy do not contract post-vaccinal encephalitis, and that, therefore, all infants should be vaccinated in order that no person above that age should by primary vaccination run the risk of post-vaccinal encephalitis (a new reason for vaccination, to protect against vaccination).

6. It is stated that their recommendations involve no material change in the instructions to vaccinators under contract—that is, they do not desire any material change in the present methods.

7. It is an expensively printed report, singularly devoid of guidance to those responsible for small-pox and vaccination administration, and though it has taken two and a half years to produce, no attempt has been made to consider the problem from a practical standpoint or to envisage the present conditions.

8. From the reply of the Minister of Health to a Parliamentary question published on the recent bank holiday, it appears that post-vaccinal encephalitis is on the increase. It is therefore a mere question of time before the persons responsible for the vaccination of those children who die of post-vaccinal encephalitis will be considered by some as guilty of constructive murder.

9. Obviously the Committee appointed by the Ministry of Health and the Medical Research Council have regarded themselves as scientific tabulators of facts and have not considered it their function to criticise the department which appointed them. What is wanted now is what I suggested in your issue of Jan. 10th, 1925—namely, a real inquiry into small-pox and vaccination administration in all its bearings by a judge of the High Court; the gentlemen of the late committee should make excellent witnesses, for on the face of their documentary evidence, the sub-department of the Ministry of Health which deals with small-pox and vaccination requires a thorough investigation as to its methods. To cite one question, what is their justification for risking children's lives by vaccination as a protection against a disease which does not imperil their lives? They have, of course, a defence; it should be set out at an inquiry, and its value assessed.

10. The report of the Andrewes Committee of 19 which only saw the light via the League of Natio about a year ago and is now published in full, sho have given the authorities furiously to think. has not done so, and it is time now that some o trained to weigh evidence and come to conclusio thereon, should envisage the whole position. No o could better decide how this is to be done than t Lord Chancellor, in his present capacity of acti Prime Minister.

11. A year ago at Hastings I stated my views the subject printed in No. 4 (1927) of the *Journal the R.S.I.* The present report and recent happeni seem but to confirm them.

12. The root difficulty has always been that t orthodox regard vaccination as a panacea of univer application, whereas it should be regarded as insurance proposition, vaccination being only t conferment of a temporary immunity from small-p which may or may not be worth while under varyi conditions. And this difficulty is aggravated the antivaccinationists who claim that vacci tion confers no protection—a manifest absurdi Supporting their views by many easily refuta arguments they lead the orthodox to a reactive bli acceptance of certain very disputable conclusions.

I am, Sir, yours faithfully,

R. W. JAMESON

West Wickham, Kent, August 14th, 1928.

EPHEDRINE.

To the Editor of THE LANCET.

SIR,—I have recently been treating several patie with low blood pressure by ephedrine hydrochlor (Burroughs Wellcome and Co.) in doses of gr. ½. the majority of cases the patients have complained giddiness and feeling ill after this. These sympto appear half to one hour after taking the ephedri and seem to last about two hours. I have fou that gr. ⅓ or ¼ seems to produce a very satisfact rise in pressure and no toxic symptoms.

I am, Sir, yours faithfully,

H. W. HALES

Sheringham, Norfolk, August 14th, 1928.

"FUSSING OVER CANCER."

To the Editor of THE LANCET.

SIR,—At the last session of the Internatio Conference on Cancer, the president warned enthusia to beware of fussing over public health, or so, least, it seems from your summary of this meet (THE LANCET, July 28th, p. 182). Point was gi to his admonition by a statement made by Dr. Star Reimann, of Philadelphia, to the effect that he co find no indication of the educational campaign of last 15 years having had any effect. And yet, if there is one point in regard to cancer on wh practically everyone is agreed, it is that the ear cancer is detected, the better are the patie chances of recovery. It might be inferred from conclusion, so obviously true as really to be a trui that cancer campaigns throughout the world wo devote much of their energies and resources shortening the interval between the first signs the disease and the treatment thereof. Why, it m be asked, is there a certain hesitancy in pursuing matter to its logical conclusion, and in launch educational campaigns with regard to canc There are two phases of the period which ends w the commencement of treatment. The first pl lasts from the appearance of the first signs of ca to the first medical examination, usually made a general practitioner. The second phase dates f this examination till expert treatment is institu For the sake of brevity, I limit myself to a consid tion of the first phase.

What are the objections to a publicity camp conducted anonymously in the lay press by

aders of the medical profession? In other words, hat is there to prevent a highly respected and presentative body of experts from issuing to the blic carefully prepared information as to the rly signs of cancer? One of the objections most mmonly raised is that such an educational campaign ould degenerate into scaremongering, and the sult would be periodic outbreaks of cancerphobia d new crops of neurasthenics. But however refully we examine the situation which would arise der such conditions, we cannot find more than o classes of persons concerned—those who are, d those who are not, suffering from early cancer. he first would surely benefit from advice which ould lead them to an early medical examination. s for the remainder, they would, if alarmed, in ost cases consult a doctor, and in due course be assured. Another obstacle to an educational mpaign is a deep-seated distaste on the part of any doctors to popularising medicine. To some is a sacred cult, not to be prostituted by widespread blicity. The situation in the world of medicine -day is curiously similar to the world of theology the time when Wesley drew his followers from the m religious light of churches to the secular atmosphere the hillside. In defence of those who shun the pular health article or lecture as they would rnographic literature, we should remind ourselves at in the past a certain amount of popular health aching has been undertaken by cranks and persons th some axe to grind. But this class has flourished rgely because the field was left open to it by the ore respectable members of the medical profession. does not, however, follow that this field ought self to be neglected. The presence in it of undesir- les should rather be a spur to replacing them by mething much better. The leaders of the medical ofession who adopt a pose of masterly inactivity this matter may find it interpreted (or misinter- eted) as a glaring example of timid indolence.

Yet another objection to an educational campaign out cancer is the lack of unanimity among the perts as to even the most elementary matters ncerning cancer. They cannot tell the public ether it is infectious or not, hereditary or not. one all-important question after another they e bound to admit ignorance. It is tempting in ch circumstances to wait and see; peradventure e cause and uniformly successful treatment of ncer will be discovered shortly, and then it will be ne enough to tell the public. To such arguments favour of silence there is the unanswerable reply at, to repeat the opening words of this letter, actically everyone is agreed that the earlier cancer detected, the better are the chances of recovery. nd if every woman is taught that a swelling in the east or an irregular hæmorrhage during the erperium needs investigation at once by a doctor r fear of its being malignant, many who at present me to a doctor for the first time with an inoperable mour would be saved. There can be no two opinions this point. Reserve on the part of the medical ofession in this matter may seem lofty and dignified a few. To candid observers it must seem merely nteel.

I am, Sir, yours faithfully,

August 11th, 1928. D.P.H.

Medical News.

MEDICAL SOCIETY OF LONDON.—The programme for the first half of the session 1928–29 has now been issued. On Monday, Oct. 8th, Dr. J. W. Carr will give a presidential address on Medical Ambitions and Ideals; on Oct. 22nd Dr. C. E. Lakin and Mr. Tudor Edwards will open a discussion on the Diagnosis and Treatment of Empyema; and on Nov. 12th Prof. Hey Groves and Dr. James Neal will open a discussion on the Medico-Legal Aspects of Fractures. On Nov. 26th there will be a clinical evening, and the last meeting of the year will be on Dec. 10th, when Dr. Wilfred Harris, Mr. P. J. Verrall, and Dr. James Brailsford will introduce the subject of Sacroiliac Pain. The Lettsomian Lectures will be delivered on Feb. 18th and 27th and March 6th by Dr. H. W. Barber, on Dermatology in Relation to other Branches of Medicine, and the Society's annual oration will be given on May 13th by Prof. Grey Turner, whose subject will be Cancer of the Colon.

MARKING OF SURGICAL INSTRUMENTS AND APPLIANCES.—The Standing Committee (General Merchandise) appointed by the Board of Trade have reported on their inquiry as to whether imported surgical, medical, dental, and veterinary instruments and appliances, and dental supplies and furniture should be required to bear an indication of origin. The report, which recommends that an order in council be made requiring the marking of many imported articles at the time of sale or exposure for sale, is obtainable from H.M. Stationery Office, or through any bookseller, price 2*d.* a copy.

ROYAL SUSSEX COUNTY HOSPITAL.—Dame Anne Beadsmore Smith, Matron-in-Chief of the Territorial Nursing Service, recently opened the two new wings which have been added to the nurses' home of this hospital. These extensions will bring the accommodation of the home up to 108 beds, and comprises rooms for the sisters and a large lecture room. A brief service of dedication was performed by Bishop Russell Wakefield, and prizes were presented to the nurses by Miss K. Scott, who has for 27 years been matron of the hospital.

ABERDEEN ROYAL INFIRMARY.—The Prince of Wales will visit Aberdeen on Aug. 28th, to lay the foundation-stone of the new Royal Infirmary. This will form part of a scheme which will coördinate in one area the services of the Royal Infirmary, the Sick Children's Hospital, the Maternity Hospital, and the University Medical School. The building will cost £400,000, of which about £326,000 has been received.

STIRLING ROYAL INFIRMARY.—The new Royal Infirmary, which was opened by the Duke and Duchess of York on August 10th, has been erected on 15 acres of ground, being part of Wester Livilands estate, which is situated to the south-west of the town. The site is an ideal one from an infirmary point of view. It forms a great, open plateau, beautifully wooded, and commanding magnificent views of the surrounding country on all sides. The building is two storeys high, and contains four surgical wards of 16 beds each, two medical wards of 16 beds each, and one children's ward of 16 beds, with small side wards in addition. The administration department is placed in the centre of the building. There is also a maternity block, which contains two wards of eight beds each, with two single wards and one two-bed ward, accommodating in all 20 patients.

CENTENARY OF ANCOATS HOSPITAL. — On August 11th, 1828, a new "public dispensary" was opened for the districts of Ancoats and Ardwick, which were then suburbs of Manchester. At that time and until about 40 years afterwards patients were treated at their own homes, while out-patients went to the dispensary for advice and medicines. There were then no arrangements for in-patients. In 1872 it was determined to add to the dispensary work "hospital practice," and in 1874 a new hospital with six beds was opened. In 1888 a new wing was added, which brought up the number of beds to 100, with developments in all branches of medical and surgical treatment. Situated as the hospital is in one of the most industrial and thickly populated districts of the city, it is now quite inadequate to the calls made on its services. An X ray department was opened in 1907 and a massage and electricity department in 1913. The board of management have determined to make the centenary celebration the occasion for an appeal for a building fund of £100,000. Land adjoining the hospital has been acquired and plans are ready for an extension with 100 additional beds, a new casualty department, extension of some existing departments, two new operating theatres, and the necessary accommodation for nurses and staff.

DEATH OF MR. T. B. LAPWORTH.—The death curred on Thursday, August 9th, at the age of 59, of . Trever B. Lapworth, who was for 44 years associated th the *British Medical Journal*, and for 17 years the head nter. He had been in failing health for some time, and ll be sadly missed by numerous colleagues and friends.

AN IMPROVED SYRINGE FOR THE TREATMENT OF RICOSE VEINS.—We understand that the improved inge which we noticed in our issue of May 19th, p. 1022, now made in capacities of 3, 5, 10, and 20 c.cm., while total length has been greatly reduced by increasing the meter of the barrel and by using only one ampulla in capillary tube instead of two as previously. The inge can be obtained from Messrs. Adair, Dutt and Co., Victoria-street, London, S.W.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

Special two weeks Course in Infants' Diseases at the Infants Hospital, Vincent-square, Westminster.

SECOND WEEK.

MONDAY, August 20th.—2 to 3 P.M., Dr. W. E. Robinson: Chest Cases. 3 to 3.45 P.M., Miss Hughes (Matron of the Hospital): Lecture-Demonstration, Notes on Nursing Sick Infants. 4 to 5 P.M., Dr. Eric Pritchard: Lecture-Demonstration, Dried Milks and Patent Foods.

TUESDAY.—2 to 3.45 P.M., Dr. Eric Pritchard: Feeding Cases. 4 to 5 P.M., Mr. Philip Franklin: Lecture, Nasal Discharge and Sinusitis.

WEDNESDAY.—2 to 3 P.M., Miss Hughes: The Making-up of Feeds. 3 to 3.45 P.M., Dr. Eric Pritchard: Lecture-Demonstration, Infants' Stools. 4 to 5 P.M., Dr. C. C. Okell (at the Wellcome Physiological Research Laboratory, 25–28, Endsleigh-gardens, Gordon-square, W.C.): Diphtheria Prophylaxis.

THURSDAY.—2 to 3 P.M., Dr. Eric Pritchard: Feeding Cases. 3 to 3.45 P.M., Dr. Eric Pritchard: Lecture-Demonstration, Minor Ailments. 4 to 5 P.M., Mr. B. S. Simmonds: Lecture, Surgical Emergencies.

FRIDAY.—2 to 3.45 P.M., Dr. Eric Pritchard: Feeding Cases. 4 to 5 P.M., Dr. M. Maizels: Pathological Lecture, The Regulation of Hydrogen-ion Concentration.

SATURDAY.—2 P.M., Visit to Model Pasteurising Plant, Willesden, and to the Nursery Training School, Welgarth-road, Hampstead.

Appointments.

CROSSE, H., M.D., C.M. Edin., has been appointed a Medical Referee for the Districts of the Aylsham, Downham Market, East Dereham, Fakenham, Holt, King's Lynn, North Walsham, Norwich, Swaffham, Thetford, and Wymondham County Courts.

FACEY, R. VAUGHAN, M.B., Ch.B. Oxf., Medical Officer in charge V.D. Department, Royal Victoria and West Hants Hospital, Bournemouth.

MUSGRAVE, J. A., L.R.C.P.I., L.R.C.S.I., D.P.H., Medical Officer of Health for the County Louth.

Certifying Surgeons under the Factory and Workshop Acts: CONNOLLY, C. V., M.B., B.Ch. N.U.I. (Rothwell); and WALKER, F., M.B., Ch.B. Edin. (Falkland, Fife).

Vacancies.

For further information refer to the advertisement columns.

Aberystwyth, Aberystwyth Infirmary and Cardiganshire General Hospital.—H.S. £200.

Bath, Royal United Hospital.—H.P., H.S., and Asst. H.S. At rate of £120 and £100 respectively.

Bedford County Hospital.—H.S., also Asst. H.S. At rate of £175 and £130 respectively.

Birmingham, General Hospital.—Med. Reg. and Res. M.O. £155.

Blackburn and East Lancashire Royal Infirmary.—Res. H.P. Also Fourth H.S. £150 and £130 respectively.

Bradford, Municipal General Hospital (St. Luke's).—H.P.'s and H.S.'s. Each at rate of £200.

Bristol General Hospital.—H.P.'s, H.S.'s, &c. All at rate of £100.

Bristol Royal Infirmary.—H.P.'s, H.S.'s. Also Dental H.S. Each at rate of £80.

Cardiff, University College.—Lecturer and Demonstrator in Anatomy. £400.

Carmarthen, Joint Counties Mental Hospital.—Jun. Asst. M.O. £300.

Chiswick General Hospital, The Mall, Chiswick, W.—Hon. Surg. Also Asst. Hon. Anæsthetist.

Colchester, Severalls Mental Hospital.—Jun. Asst. M.O. £510.

Croydon County Borough.—Asst. M.O.H., &c. £600.

Dreadnought Hospital, Greenwich.—Surg. to Out-patients.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. At rate of £100.

Grove Park Hospital, Lee, S.E.—Sen. Asst. M.O. £650.

Hastings, Royal East Sussex Hospital.—Hon. Co-opted Dental Surgeon.

Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—H.P. At rate of £110.

Ilkeston, Borough of.—M.O.H. and School M.O. £800.

Kingston-on-Thames, Surrey County Sanatorium, Milford, near Godalming.—Sen. Asst. Res. M.O. £500.

Leicester, City Education Committee.—Asst. School M.O. £600.

Leicester Royal Infirmary.—Res. M.O.'s. Each at rate of £125.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

Manchester, Hulme Dispensary, Dale-street.—Res. M.O. £300

Manchester, Park Hospital, Davyhulme.—Three R.M.O.'s. C at rate of £150 and two at rate of £120.

Market Drayton, Salop, Cheshire Joint Sanatorium.—As M.O. £250.

Newport, Mon., Cefn Mably Hospital, Michaelstone-y-vedw Asst. Res. M.O. £200. Also Third Asst. Res. M.O. South Wales Sanatorium, Talgarth, near Brecon. £200.

Norwich, Norfolk and Norwich Hospital.—Hon. Asst. Phys.

Nottingham City.—M.O.H. £1440.

Nottingham City Mental Hospital.—Jun. Asst. M.O. £350.

Plymouth, Homœopathic and General Hospital.—H.S. At rate £100.

Plymouth, South Devon and East Cornwall Hospital.—H.S. rate of £50.

Rotherham, Rotherham Hospital.—H.P. £180.

Samaritan Free Hospital for Women, Marylebone-road, N.W. H.S. At rate of £100.

Southampton Parish Infirmary, Shirley Warren.—Second As Res. M.O. £275.

Swansea General and Eye Hospital.—Sen. Res. O. £250.

Wandsworth Borough Council.—Locum Tenens, Asst. M.O.I &c. £10 10*s.* weekly.

West London Hospital, Hammersmith-road, W.—Non-Res. Cas. £5 5*s.* per week. Also H.P. and two H.S.'s. Each at r of £100.

Western Australia Lunacy Dept.—Jun. Asst. Res. M.O. £456.

The Chief Inspector of Factories announces vacancies Certifying Factory Surgeons at Eastbourne, Sussex; a at Wendron, Cornwall.

Births, Marriages, and Deaths

BIRTHS.

CARSON.—On August 2nd, the wife of Dr. Hugh Carson, t Hospital, Selly Oak, Birmingham, of a daughter.

GILES.—On August 9th, at York House, Stourport, Worc the wife of Dr. O. Pemberton Giles, of a son.

MATHEWSON.—On July 31st, the wife of Dr. W. R. Mathews Netherhill, Aberdour, of a daughter.

ROBB.—On August 12th, at Lodge Farm, Melton, Suffolk, t wife of Captain Campbell Robb, R.A.M.C. (retd.), of a s

RUSSELL.—On August 4th, at Tooting Bec-gardens, Streatha S.W., the wife of Dr. C. M. Russell, of a son.

TIVY.—On August 7th, the wife of Dr. Eric Tivy, of No Woolwich-road, Silvertown, of a daughter.

TODD.—On August 10th, at Cuckfield, Sussex, the wife H. C. Todd, F.R.C.S., of a daughter.

WHITEHEAD.—On August 4th, at York Mansions, S.W., wife of Major N. T. Whitehead, R.A.M.C., of a daugh (stillborn).

MARRIAGES.

ARNOTT—HOWDEN.—At St. Columba's Church, Crieff, Per shire, on August 8th, by the Rev. N. J. N. Gourlie, M. Maurice James, only son of Dr. and Mrs. James Arnott, Brampton, Cumberland, to Jean Skeffington, elder daugh of Emeritus Professor and Mrs. Robert Howden, of Broc field, Crieff (formerly of Newcastle-upon-Tyne).

CAPELL—DREW.—On August 11th, at St. Mary Abbots, Kensi ton, Dr. L. F. Capell, of Cricklewood-lane, N.W., to Doro Edith, only daughter of the late William Godson Drew, Hove, Sussex.

LORRAINE—WILSON.—On August 9th, at St. Mary's Par Church, Knebworth, J. C. Lorraine, M.D., F.R.C.S. Ed of Montpelier-square, S.W., to Alicia Hill, daughter of and Mrs. Wm. Wilson, of Knebworth.

SELLORS—LYELL.—On August 8th, at St. Jude's Chur Kensington, Thomas Holmes Sellors, B.M., B.Ch., M.A. Brenda Murray, daughter of Mrs. W. D. Lyell, Courtfie gardens, S.W.

THOMAS—NEWCOME.—On July 31st, at St. Gabriel's Chur Warwick-square, London, Ellis Rae Thomas, M.D., M.R.C. L.R.C.P., to Lilian Gladys, fourth daughter of the l Chester Pern Newcome, of Long Clawson, Leicestershire

DEATHS.

CAMBRIDGE.—On August 12th, at Crouch Hill, Thomas Arth Cambridge, M.R.C.S., L.S.A., aged 82.

CHILDS.—On August 6th, at Rock House, West Looe, Cornw Christopher Childs, M.D., aged 81.

DAVIDSON.—On August 11th, at Over Frays, Uxbridge, Jo Davidson, M.B., aged 70.

EASTES.—On August 8th, at Manor-road, Folkestone, Thor Eastes, M.D., aged 78.

GREY.—On August 10th, at Harrold, Bedfordshire, sudden from pneumonia, Egerton Charles Grey, M.A. Can D.Sc. Lond., M.R.C.S., L.R.C.P., F.I.C., late of Cairo.

KERSWILL.—On August 10th, at Sackville House, Sandwi Harry Kerswill, M.R.C.S., L.R.C.P., aged 60.

OAKDEN.—On August 12th, William Marshall Oakden, B. M.B., B.Chir. Camb., F.R.C.S. Eng., Medical Superintend of St. Luke's Hospital, Lowestoft, aged 41.

TUXFORD.—On August 8th, at Wide Bargate, Boston, Art Tuxford, J.P., M.D., aged 87.

WHERRY.—On August 12th, at Cambridge, George Edw Wherry, F.R.C.S., aged 76.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notice Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

NOTES ON THE SLACK ABDOMINAL WALL.

LIEUT.-COLONEL J. K. MCCONNEL, D.S.O., M.C.,
MEMBER OF THE CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.

THE following aims at placing the treatment of this con-
ion on to a scientific basis; it is hoped thus to avoid the
icism in Allbutt and Rolleston's "A System of Medi-
e": "The treatment ceases and, when a sufficient time
elapsed to undo the good which has been done, the
ient becomes as bad as ever." The writer asks forgive-
s for the extensive quotations in the following lines,
he feels it important to base his arguments on sound
hority.

When one investigates this subject, one is in danger of
oming bogged in the voluminous literature that discusses
sis of the abdominal contents—either severally or
ectively. A direct attack on the viscera themselves has
led to very gratifying results and, as is stated in "Modern
licine" (Osler and McCrae): "The treatment is in the
n rather unsatisfactory. . . ."

n order to concentrate our attention on the musculature
he weak abdominal wall, let us take as a simile a motor
e in which a bulge has appeared. Supposing one finds
replacement at the nearest garage, one may instruct the
chanic to insert a sleeve between the two tubes. In
se circumstances no one would blame the air inside for
ing caused the distressing symptoms, but one would
one's best to overcome the defect in the outer cover and
der it an adequate support for its contents.

n the same way several authorities have noted the
appearance of symptoms of visceroptosis, when a suitable
port has been applied. Prof. Starling stated: "These
cera in the normal condition are pressed against the
ler surface of the diaphragm by the elasticity of the
lominal wall." Sir Arthur Keith[1] states: "Now, as is
l known, when a living subject raises his body to the
ing or standing posture, the upper viscera do not drop
re than ½ or ¾ in.; the ligaments and mesenteries can
refore take no part in sustaining the viscera. The
porting structures are the muscles of the belly wall;
ticularly is the transversalis muscle important in this
pect; it is a living belt which girds the loins."

Let us now leave the viscera and turn our attention to
abdominal wall.

Muscle Action.

Before pursuing the argument it seems advantageous to
mmarise certain characteristics of muscles. Prof. Starling,
his "Principles of Human Physiology," wrote as regards
scular tone: "Every muscle in the body is in a condition
slightly continued contraction which keeps it tense,
that when it contracts in response to a stimulus, there is,
to speak, no "slack" to be taken up before the muscle
ins to pull on its attachments. . . . The tone of the
scles is a reflex phenomenon and is dependent on the
egrity of the reflex arc governing the muscles in question.
has been shown by Sherrington that the afferent part of
arc is represented by the afferent nerves from the muscle
lf. . . . To this system of afferent nerves Sherrington
given the name of the proprioceptive system, since it
xcited, not directly by changes in the environment, but
alteration in the animal itself."

A muscle may act in four ways. It may remain at rest,
y contract, may "hold," or may relax. Patients some-
es think that muscles can push; at least, they explain
vements in terms that would necessitate this. Con-
ction may take place actively, as when causing a move-
nt, or as a passive shortening, when the energy required
a movement is supplied by some outside force—e.g.,
vity—another person, a spring, &c. During an active
traction energy produced by a muscle is impressed on
system to which it belongs through the medium of its
achments or else hydrostatically. As an example of
latter we may take: "The contractions of the skeletal
scles squeeze the veins contained within them, and
ve the blood on towards the heart."[2]

Following the classification of muscles in a normal act[3] as
en by Dr. Kinnier Wilson, we find:—

. *Prime movers, or agonists*, which initiate the act.

. *The antagonists*, which would tend to interfere with the
ve movement, if they were not reciprocally inhibited.

. *Synergic muscles* (synergists), which neutralise undesired
ions, as when a prime mover, by passing over two or more joints, might give two or more actions, one being desired.

4. *Fixation muscles* (fixers), which provide firm origins from which the others may act.

In a firm closure of the fist the agonists are the flexors of the thumb and fingers, and antagonists are the extensors of the same; as synergists we find the extensors of the wrist, and as fixers the flexors and extensors of the elbow and many other muscles as well. Movements of coöperation also take place;[2] of these one may mention arm-swinging in walking.

The Abdominal Wall as a Muscle.

Turning now to the behaviour of the abdominal wall as muscle, we find its activities intimately related to other groups of muscles. We see a "great cylinder" (Keith), the sides of which are formed by the erector spinæ, quadratus lumborum, and the abdominal wall, while the top and bottom are imperfectly closed by the diaphragm and the pelvic floor. Sir Arthur Keith states: "We are apt to forget that the chief muscles of the belly wall, the two recti, the external obliques, and the internal obliques are primarily muscles of the spine; they are powerful postural antagonists of the component elements of the erector spinæ muscles. . . . The student is so apt to concentrate his attention on the respiratory action of the ribs that he forgets that they are the most powerful of the spinal levers. All the muscles attached to the ribs—the intercostals, the rectus abdominis, and oblique muscles of the belly wall—are prime movers and balancers of the spine."[1]

The abdominal wall, being antagonistic to the diaphragm, acts as a respiratory muscle; it contracts during expiration, forcing the latter up, the energy being transmitted hydrostatically. Prof. Starling wrote: "In fact, Sherrington's results on the coördination of muscular movements would tend to make us assume inhibition of the tone—e.g., of the abdominal muscles, during inspiration, and active augmentation of tone during expiration. Where the tone of the muscle is entirely lost—e.g., in the condition of visceroptosis—it has been observed that the diaphragm is thrown out of action, breathing being chiefly carried out by an elevation of the upper part of the thorax."

We must now refer to the action of the abdominal wall in a movement which may be termed "flattening out the lumbar curve," as it will be made use of during treatment. It can take place in any position, but one should realise that, unless the lumbar erector spinæ relax reciprocally, it cannot occur. During this movement the abdominal wall is normally the prime mover, but in certain positions, such as lying supine or reclining in a chair, gravity assists and, in fact, may supply the entire energy requisite for the movement, while the abdominal wall merely shortens passively. Under some conditions the movement is assisted by contraction of gluteus maximus and the hamstrings. When the action of these muscles becomes of importance, it will be seen that the movement approximates to a rotation of the pelvis, and that this rotation would, for instance, in the standing position, take place about an axis drawn through the hip-joints, whereas in other positions a variation from this axis would occur. For practical purposes this rotation, which is an important factor in treatment, may be described as "turning the tail between the legs," and it is interesting to notice the coöperation between the abdominal wall on the one hand and the gluteus maximus and hamstrings on the other. The rotation may be readily perceived by laying the hand on the sacrum, though not, however, on gluteus maximus, if this latter is strongly developed.

One further point before passing on: Should a patient maintain a contraction of the erector spinæ, make a contraction of the abdominal wall and, at the same time, hold his breath, one then observes that his chest is forced up. This combination of muscle actions frequently occurs when a patient tries to flex or to flatten the lumbar spine.

Tone.

As regards the tone of the abdominal wall, Sir Arthur Keith[1] states: "The moment we assume a sitting or a standing posture there is set going a reflex mechanism which throws the muscles of the belly wall into a state of postural tone." This, of course, refers to the normal individual who has a satisfactory abdominal wall. From earlier quotations we see that this tone depends primarily on proprioceptive impulses from the constituent muscles themselves, and should note that the alternate inhibitions and augmentations of tone reciprocally in relation to the diaphragm tend to keep the abdominal wall in a healthy state.

In one type of individual we find a slack abdominal wall associated with a marked lordosis or increase of the lumbar curve. As regards the obese variety of this type, there is, in Dr. W. F. Christie's "Surplus Fat and How to Reduce it," a clever sketch entitled, "Election Day at the Fat Man's Club." The next gentleman to enter in is depicted

sideways on, displaying a magnificent "object in view," as a large tummy is sometimes called, and one notices a strongly developed lordosis. It has been found that a proportion of this type, both the obese and the thin varieties, suffer pain in the lumbar region, and often it is for this reason that they submit themselves for treatment. This pain may arise in the joints—vertebral or sacro-iliac—or else in the muscles and surrounding structures; if in the latter, it is due to the presence of waste products, to strain or to spasm required for the fixation of painful joints, and in any case a lack of coördination of the constituents of the muscle group is likely to be a factor of some importance.

Anyone who wishes to appreciate the condition of this type of patient should clasp with both arms a heavy weight, holding it about the level of the umbilicus, and walk upstairs. Balance is preserved by canting the upper part of the body backwards, maintaining this attitude by a contraction of the lumbar muscles. After mounting several flights of stairs in this way a pain in the back may become quite noticeable. When a group of muscles finds itself antagonistic to another strong group held in contraction, its tone tends to be inhibited. Such an inhibition of tone tends to be forced on the abdominal wall whenever the lumbar muscles are held in spasm. It will thus be realised that normal activity of the abdominal wall in relation to the diaphragm tends to improve the tone of the abdominal wall, whereas spasticity of the lumbar muscles tends to depress it.

Another type of individual has a thin and sagging abdominal wall, but without any undue lumbar curvature or, in fact, with a deficiency thereof. As a rule, the cervical curve is exaggerated (ewe-neck) in order to assist in giving a horizontal line of vision, the tilt of the eyes, the relation of occiput to atlas, and the dorsal curve being variables in this respect. As will be shown later, the proprioceptive messages from the prevertebral cervical muscles are an important factor in the tone of the abdominal wall. In this type of patient the abnormal balance between the post and prevertebral cervical muscles is the key to the situation.

We must refer briefly to alterations of tone of the abdominal wall due to impulses which arise in the afferent nerve-endings of the viscera. On the one hand, rigidity of the former is a well-recognised symptom of acute conditions in the latter, while on the other hand Sir C. Sherrington demonstrated that when the afferent nerves from the viscera are severed, the abdominal musculature loses its postural tone.

Posture.

"In the maintenance and recovery of posture many separate types of reflex converge to produce a common result, and these reflexes arise from such sense organs as the labryinth, the eyes, and the muscles themselves. The removal of the central hemispheres has but little effect on normal posture or on righting reactions by which that posture is resumed after having been interfered with. It is clear, therefore, that these reactions are true reflexes, and it would be quite wrong to imagine that the animal knows that its posture is being upset, resents interference, and voluntarily acts in such a manner as to counteract the offence." [4]

"Consciously, we are in complete ignorance of the specific muscular units effecting a 'voluntary' movement. . . . The point at present is that a very large part of every 'voluntary' movement is both 'involuntary' and outside consciousness." [3]

Prof. Magnus's researches have classified these reflexes in terms of the organs from which the stimuli arise, also as to whether they refer to movement (stato-kinetic) or rest (static), both as regards "pose" or "righting." "In general we can say that by means of the stato-kinetic reflexes the body is brought into its normal pose, which pose is maintained by the operation of the various static reflexes. It will have been noticed that the head plays an important part in deciding most of these responses. The head contains the organs of special sense, particularly the distance receptors for sight and sound, so that the head tends to be voluntarily directed towards stimuli which affect these sense organs. The proper orientation of the remainder of the body which ensues is effected by the action of the various reflexes which have been described." [4] Dealing with the same subject, Prof. Starling wrote: "In the evolution of the nervous system there has been a continual subordination of the hinder parts to the head end, in consequence of the development at this end of the all-important distance receptors, the impulses from which take a predominating part in determining the reactions of the body as a whole."

Dr. Kinnier Wilson's example of muscle action, when firmly closing the fist, may be amplified. If it took place in a standing or sitting position, the muscle action of the trunk, coördinated to maintain posture, would be synergic and also would fail to obtrude into the field of consciousness. The man would not notice the pose of his body, which would be taken up in accordance with his normal habit.

Sir Arthur Keith [1] points out that the spine of the human baby changes from the primitive curve in the second year of life, and adopts the lumbar curve. This alteration takes place through the medium of the spinal muscles—the spine's balancers. We must not consider this lumbar curve as fixed, but rather as varying continuously to suit the requirements of the moment. The same applies, and even more so, to the relative tension of the balancing muscles. One might argue that, while this curve is being established, consciousness takes it into account, but certainly later it passes unnoticed, unless commented on by a parent. The child is consciously concerned with his hand movements, &c., and only gross mis-balances of the lumbar and abdominal muscles are recognised. We thus see that it is possible for an undue contraction of the lumbar muscles to arise in early youth and develop, so to speak, along with the child; this contraction would merely be a failure to adapt the body to its environment. The so-called "pot-bellied" type of child constitutes a more serious condition than the above; the disturbance in this case is probably visceral in origin.

As a rule, it is probable that a lumbar spasm, as we now can term it, arises as a secondary condition to a mal-posture of the shoulders and dorsal region. The child gets tired either when standing or sitting; the shoulders droop and the dorsal region becomes round. The parent or teacher thinking of the contracted chest, says "sit up," directing the child's attention to its head and also, perhaps, to its shoulders. As the levator anguli scapulæ rhomboid serratus magnus sheet of muscle, as well as the dorsal muscles, are tired, the child compensates in the easiest possible manner, namely, by contracting the lumbar muscles and, by inducing a lumbar curve, makes the dorsal curve less apparent and the cervical lordosis (ewe-neck) less pronounced—". . . sitting bolt-upright is particularly exhausting, especially for young people . . ." (Keith.)

When dealing with patients who have a slack abdominal wall, it is usually noticeable that, in the erect position, attempts to flatten the shoulders or decrease a dorsal curve are not limited to the correct muscles, but irradiate downwards to the lumbar area, or sometimes upwards to the cervical region. Before treatment they are virtually unable to contract alone the dorsal muscles; this is so even after the movements concerned have been performed passively to ensure they realise what is required.

Brief reference must be made to conditions that may arise subsequent to pregnancy; treatment is discussed in "A Textbook of the Practice of Medicine" (F. W. Price). It appears that the lumbar spasm—accompanied by pain in the back—which is so often a feature of the last few months of pregnancy, occurs in the effort of preserving balance when walking or standing. In some cases the postural habit persists after childbirth, although the stimulus which gave rise to it is no longer present; such conditions as tender sacro-iliac joints, if inadequately supported, would encourage this persistence. It is suggested that the lumbar spasm militates against and tends to delay the recovery of the stretched abdominal wall, the proprioceptive impulses from the former tending to reduce the tone of the latter.

Proprioceptive impulses from the neck muscles have already been mentioned as a stimulus which increases the tone in the abdominal wall. Prof. Magnus's cinematograph films of falling cats, which showed the head righting first and then the body, indicate a chain reflex compounded from a labyrinthine reflex as regards the head and a neck reflex as regards the body. When teaching a horse to correct "reining back"—the forefeet moving first, so as to arch the spine and necessitating a full contraction of the abdominal wall—one notices the extreme importance of a correct muscle balance in the neck. When teaching patients a good neck posture they frequently, on their own initiative, draw attention to the increased tone in the abdominal wall, which accompanies their newly-acquired neck movement. This can be demonstrated both when lying and when erect; it is certainly not merely a transient stretch reflex. Unfortunately, little research seems to have been done on this point, but it appears certain that the neck reflex which accompanies a good neck carriage is an important factor in human posture.

Sir Arthur Keith draws attention to the difference between a power of voluntary contraction and a condition of postural tone. An abdominal wall may be excellent when voluntarily contracted, and yet a few minutes later, when the patient's attention has been directed to something else, it may revert to "C3" as regards postural tone. We can state the conclusion that a posturally slack abdominal wall is associated with either an undue lumbar spasm or a deficient tone in the prevertebral neck muscles, or with both. Healthy exercise in relation to the diaphragm helps to maintain the abdominal wall in good condition and delay its degeneration. Teaching relaxation of the antagonist is the first principle of re-education as laid down by Dr. J. B. Mennell; [5] it

doubtedly the first step in a rational treatment of a slack dominal wall.

Reflexes.

We find ourselves faced with a problem of postural exes and, in order to follow the subject to its logical nclusion, we must invoke the aid of Prof. Pavlov's earches, from which we can obtain valuable assistance. s not easy to recognise at first sight exactly with what we dealing; for instance, the supposed inborn reflex which vlov extensively employed—namely, the "salivation animals on sight and smell of meat—is not an inborn unconditional reflex, but an acquired one."[4] it is bable that it is predisposition to such a reflex which is nsmitted by heredity. Are we dealing with an inborn lex in the case of the lumbar muscle tensions or in the e of belly wall (see previous quotation from Keith)? so, to what extent are they inherited, and how much nditioned by the experience of the individual?

n point of fact Pavlov himself inhibited an inborn reflex means of another one, as he records in his work "Conioned Reflexes." As Prof. Starling stated: "It is ever possible to extinguish artificially a (conditioned) ex in the course of a few minutes. Such an experimental inction of conditioned reflexes can be obtained by anging the conditions of the experiment, so as to break first law of conditioned reflexes, namely to use the nditioned stimulus several times in succession without nbining it with the unconditioned stimulus." Thus the leterious effects of either type of reflex can be got over en desirable, but we must beware of inhibiting inhibitions ich we are trying to establish.

Let us take it that, at the present stage of the development of our race, the muscular contractions inducing those mpensatory spinal curves which are designed to keep the ad level, &c., in the most satisfactory manner, are an herited reflex. Groups of stimuli from the labyrinth, k, &c., that arise on the assumption of the erect position, in relation to the above. In the normal human being erect position evokes an increased tone in the belly ll (Keith). We must remember that from the assumption the erect position there does not result just a single mulus but a group of stimuli, some or other of which y predominate in each individual. Pavlov found that h factors as old age, pregnancy, distension of the bowels, health including digestive troubles, drugs such as caffeins, mides, alcohol, &c., altered the relative intensity of itation and inhibition. Under these conditions it is iple to imagine how the normal reflex in relation to the ct-position group of stimuli becomes inhibited and at t some, then more, of these stimuli come to "condition" increased tone of the lumbar muscles and to have a iprocal effect on the abdominal wall, as already described.

Treatment.

The outline of treatment consists of dissociating the stural stimuli from the patient's undesirable postural tor reactions, and then linking them up with those that more satisfactory. The patient practises on the one nd, the required muscle actions—individually or in ups—in positions in which the postural stimuli of the ct position either do not operate or are naturally inhibited. the other hand, the same postural stimuli are allowed act under temporal or spatial conditions, in which they not call forth his undesirable reactions. Thirdly, the tient is shown how to encourage the linkage of stimuli with satisfactory posture. Besides this he must appreciate m the outset how to avoid undoing the results of his rts during the intervening periods, until the new postures ome automatic when conscious effort is no longer quired.

The use of stretching exercises to deal with spasticity the lumbar region would not appear to produce the best ults. As a rule, forcible stretching is not required and it were, the patient's condition would probably lead to eing contra-indicated. It is far wiser to teach a relaxation d trust that such stretching as is necessary will come with proved function.

Following the lead of Pavlov's work, we see the importance the "erect position" being really a group of conditioned muli instead of being a single one. A man who has just rnt to relax his lumbar muscles when sitting in a certain air may not be able to repeat this under slightly different nditions—e.g., in a chair with a lower seat or back at a ferent slope. He certainly cannot repeat the relaxation once when standing; this is important, because patients inclined to try and estimate progress when standing at the termination of a treatment. Pavlov shows that th dogs, stimuli from other parts of the brain effect nditioned reflexes both as regards synthesis and inhibition with human beings this must occur to a still greater ent—thus the memory of failure or success in a movement exercise may make a vast difference to results. In this stural work one finds that what suits one patient is virtually useless with another, although the conditions appear to be almost identical.

From the foregoing one can guess that exercises in the erect position should be given with caution at first. In "sitting" one can use from the outset certain relaxation postures and exercises, but in "standing" anything of the kind is contra-indicated, as it would tend to inhibit the inhibition we are developing. Certain uncommon positions are of extreme value, as for instance, "hands and knees"; provided the heart, &c., permit, there appears no objection to the assumption of this position, as patients over 70 years old, and others over 20 stone, have taken to it eagerly. These uncommon positions have an advantage of being a virgin field as regards stimuli; in them the stimuli have never been wrongly connected and so do not require to be inhibited. Lying positions are of the greatest importance, as is so strongly advocated by Dr. Joel E. Goldthwait.

One must say, however, that it is essential to connect what is learnt in the above positions with what one wishes to take place in "standing" or "sitting." This can be done either by a steady transition from one position to another, or by the patient grasping a similarity of joint movements, muscle actions, &c., noting the varied effect of gravity on the different parts of his body. Another useful method is to arrange that the contractions of the postural muscles are synergic to other muscles, whose activity is for the moment vividly within the field of consciousness. Synergism is thus used as a stepping-stone between voluntary effort and normal postural activity. Incidentally, in this way, a patient is led on from the idea of a correct posture, when his body is at rest, to one when he is in motion.

As Prof. Starling wrote: "The shorter the intervals between the successive presentations of the conditioned stimulus the quicker the extinction." This, of course, applies equally to the re-synthesis. "A conditioned reflex which has undergone such extinction, however, regenerates spontaneously after a few hours. . . . Repeated extinction has much more profound effect, and the spontaneous regeneration of such reflexes is progressively slower and less complete so that after having undergone several extinctions, the reflex disappears altogether."[4] Tri-weekly, or even daily, treatment in gymnasiums where patients undertake complicated exercises, difficult to repeat except under the eye or with the help of a gymnast, do not appear likely to give the optimum results. To obtain these, it seems best to visit the patient and work in his own study and/or bedroom, so as to show him exactly how to use his own chair, sofa, &c., to the best advantage. "Little and often," as Dr. J. B. Mennell points out, should be the rule; practice at decreasing intervals soon makes a posture automatic and re-establishes a good habit. One must show the patient movements and relaxation postures applicable to various occasions, those for before rising and after retiring, those for use when turning over a leaf of his paper, when strap-hanging in the tube, sitting in the car or bus, when "dummy" at bridge—no one would notice that a curative process was in progress, so there would be no cause for comment or laughter.

Reference has been made to relaxation postures. These are most important. As examples, one may cite: sit with one's feet on a footstool so as to avoid an undue lumbar curve; have a pillow under the knees if taking breakfast in bed; lie on one's side with the knees drawn up, especially if this is associated with "turning the tail between the legs." This tilting of the pelvis is of course one of the most valuable movements. Many patients are unable at first to contract gluteus maximus or the hamstrings to assist in the movement. In this case contraction of the specific muscle is best learnt alone—for example, when reclining against pillows in bed, straighten out the hip-joint and slide down in bed. No one, unless paralysed, &c., could fail to do this simple movement, and the required contraction, after having been felt, can be performed in other positions and in combination with that of other muscle groups.

Looking glasses are useful during treatment, as ocular demonstration has a great power of suggestion. The usual three-quarter length wall-glass and a hand, or other portable, mirror will suffice; they are especially valuable when teaching neck postures. Shadowgraphs and a blackboard have been advocated for postural instruction.[6]

The number of treatments required depends largely on the voluntary control the patient has over his various muscles. An incoördinate patient who has never been accustomed to games of skill will take longer, especially if he has extreme weakness of the abdominal wall and spasticity in the lumbar region, than one who has to some degree trained for sport or athletics. Additional disturbances, such as round shoulders, a contracted chest, especially in elderly people, increase the difficulty of obtaining a satisfactory result and, consequently, the length of treatment. Sometimes it is found that even a couple of treatments suffice to put a man on the right road so that he can

continue to develop good habits by himself. It is taken for granted that during a treatment of the nature described in these notes, the medical practitioner in charge of the case will prescribe such medicinal or other treatment as he deems advisable. One must add, in conclusion, that the feeling of well-being that comes from an improvement in portal circulation and greater activity of the abdominal wall is sufficient incentive for a patient to continue the slight amount of effort that is needed.

I am permitted by Sir Arthur Keith to say that, in his opinion, facts are brought to light in this communication which would be useful in practical therapeutics, and which, while well known to workers along the special line, are not necessarily equally well known to practitioners. This has encouraged me to publish the notes.

NAVAL TRAINING ASHORE.

THE good training ship, H.M.S. *St. Vincent* (Portsmouth), seems like Antæus to have gained fresh vitality since it touched mother earth and took over the old Marine Barracks at Gosport. Surgeon-Commander H. W. Nicholls tells in the *Journal of the Royal Naval Medical Service* for July of the comfort and care which surround these bluejacket boys, of whom there are at present about 600. During a nine months' stay a boy adds on the average 8 or 9 lb. to his weight and 2 to 3 inches to his height. The boys are housed in four blocks, with a separate building for new entries. Heating is by radiators throughout; in winter dormitories are warmed up from 2 A.M. until the boys have finished dressing and fires are lighted early in the school rooms for the work which is done there before breakfast, Commander Nicholls believing these early hours to be the danger period. Special attention is given to providing green vegetables which he finds discourage boils. The routine baths are hot and cold showers, and are fully used, voluntarily, too, after games. Physical training, in which games play a large part, produces remarkable results; the boys take quickly to hockey and Rugby football, but some prefer reading, and there is no compulsion. There is a covered swimming bath. Among new entries there were seven cases of mumps, four of scarlet fever, in nine months; apparently none among "old boys." There are 26 beds in the sick bay; work in the ship is strenuous, and the common form of "going sick" is a tiredness which is slept off in 24 hours, duty being resumed in 48. Recruits are coming in more from Gosport now, where parents see how well off the boys are. The medical officer notes with admiration their ability to eat a two-course dinner in seven minutes, without ever a complaint of indigestion. It is pleasant to know that another wooden training ship, with its risk of infection from confined space, has been disestablished. Ut exeant omnes!

IS THERE A NEUROTROPIC SPIROCHÆTE?

MANY of the reports on acquired syphilis in family groups emphasise the frequency of neurological complications, and invoke the influence of a so-called neurotropic strain of *Spirochæta pallida*. H. Noguchi and other workers distinguished this strain from the "dermatropic" by its size and variations in its incubation characteristics in experimental animals, as well as by its results. There is a school of thought which holds that infection from a common source tends to produce the same type of syphilis in all who catch it. A number of investigators, however, believe that the soil is more important than the parasite in determining the form of the manifestation. The former produce evidence of the disease, taking the same form in husband and wife; J. E. Moore and A. Keidel studied 111 married couples and found that in 57 per cent. of the cases with parenchymatous neurosyphilis the partner also had neurosyphilis in some form. A similar experiment at the Mayo Clinic, however, only yielded 22 per cent. of positive results.

In order to see what evidence could be produced on the other side, that of the predominance of family characteristics, Dr. P. A. O'Leary and Dr. M. W. Rubenstein have investigated [1] 13 families whose members had acquired syph from different sources. They eliminated patients with a signs of congenital syphilis or parental history before birth of children, and exacted clinical and serological evide of syphilis, and a history of chancre followed by second signs. There were four groups of sisters, two of broth two of brother and sister, two of mother and son, two mother and daughter, one of father and son, and one mother, son, and daughter. In seven families more t one member, in two neither member, and in four fami one member only had neurosyphilis.

Although these observers agree that trauma, dise virulence of the organism, and the type of treatment important factors, they see in their results evidence for greater importance of the family characteristics. T results of treatment gave a more striking indication the working of this factor, for in five out of the se families with neurosyphilis all the members respon favourably, while in the other two none responded. T conclusion seems to be a sensible one, but the smallness the number investigated throws doubt on the eviden value of the experiment.

NEW PREPARATIONS.

Eukodal.—This analgesic preparation, supplied H. R. Napp, Ltd., 3 and 4, Clements Inn, Kingsw London, is introduced as an ideal substitute for morphi Codein is not held to be dangerous as an addiction dr and has been excluded from the Dangerous Drug A The formula is given as dihydroxy-codeinon hydrochlori and it is claimed both to be an excellent substitute morphine and of great value when used in conjunction w morphine. The narcotic and analgesic effects are produ when the drug is administered orally, where its employm is specially recommended for allaying irritative cou while to meet cases of pain subcutaneous injections may employed.

The same firm sends us a new theobromine preparati *Theosol*, whose full formula is theobromine calcium s cylate, a formula which explains the intentions which h led to the preparation of the drug. The indications for use are probably familiar to many of our readers; t combination has been recognised of value in arterio-scler and asthma of the cardiac form, and is also found to poss diuretic qualities.

LONGEVITY.

THE *Times*, on August 13th, devoted a leading art to Mr. Li Ching Yun, who is alleged just to have celebra his 250th birthday, the representative of the *North Ch Herald* having visited him and found him quite well. name is at any rate worth putting on record, Thomas Parr with his 153 years is put completely in shade. Some people are doubtful of Parr's credent but in December, 1926, the death was reported at C stantinople of Zaro Agha at the age of 153, and ment was made then of Teku Oglu Ali Agha, aged 147. November of that year, also, the death was reported, at age of 135, of Maria Ustav, in Carcaliu, Tulcea, Dobr Roumania, who lived on vegetables and fish and wa strict teetotaller, but no doubt consumed the soured r of the country to which the number of centenarians Bulgaria and Roumania is largely attributed. It is sumed, of course, that the Chinaman has not been celebra his birthday every six months.

INADVERTENCE.

IN reply to natural expostulation we admit that advertisement wherein an impossible virtue was claimed a particular ointment was inserted without due attentio its contents. We much regret the inadvertence.

STUDENTS' GUIDE—SESSION 1928-1929.

ENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION.

THE General Council of Medical Education and egistration of the United Kingdom is, first, a gistering body: no person, even though his qualifica-ns have been obtained by examination, is a *legally alified* medical practitioner until his name appears the Medical Register. Secondly, it is a standard-ng body, ensuring that medical education reaches an icient minimum standard by scientific examination. irdly, it is a penal and disciplinary body, having wer to remove from the Register any practitioner nvicted of felony or misdemeanour or adjudged guilty professional misconduct. Fourthly, to the Council committed the codification of pharmaceutical medies. The duties of the Council are thus primarily a public nature, and its construction shows its ness for its fourfold responsibilities.

The Council consists of 38 members, of whom all t 11 are official representatives of some corporate dy. Five members are chosen by the Crown on the lvice of the Privy Council, and six others are elected the members of the medical profession as Direct epresentatives. The Crown members need not be edical men and one layman now sits on the Council. ree members are appointed for dental business by e Privy Council under the Dentists Act, 1921, der which the powers and duties of the General edical Council with regard to the keeping of the entists Register and the administration of the entists Acts were largely transferred to the Dental oard of the United Kingdom.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional udy after registration as a student occupies at least ve years. The Final Examination in Medicine, rgery, and Midwifery must not be passed before the ose of the fifth academic year of medical study.

Regulations as to Registration of Medical Students.

Before registration as a student every candidate ould produce evidence that (*a*) he has attained the ge of 17 years; (*b*) that he has passed a recognised amination in general education; and (*c*) that, *addition thereto*, he has passed, or obtained emption from, an examination, theoretical and actical, in elementary physics and elementary emistry conducted or recognised by a licensing dy. The minimum standard of General Education quired is that of University Matriculation or ntrance examination in the Faculties of Arts or ure Science. In other Faculties the examination ust be of the standard prescribed in Regulation 2 elow.

An approved course of instruction in elementary iology at a secondary school or other teaching stitution recognised by a licensing body may lmit a student to the professional examination in ementary biology upon registration as a medical udent.

The candidate commencing medical study should pply to the registrar of the division of Great Britain nd Ireland in which he is residing, according to a rescribed form, copies of which may be had on pplication to the several licensing bodies, medical chools, and hospitals, or at the offices of the Council; nd should produce proof that he, or she, has fulfilled he first three conditions.

The Maintenance of the Register of Medical Students.

1. The Education Committee prepares and issues from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are specially recognised by, the Council.

2. The Council has recognised the undernoted university examinations which are conducted in Great Britain and admit to the Faculties of Arts or Pure Science, or to other Faculties, subject to the conditions specified below:—

Oxford University, Responsions; Cambridge University, The Previous Examination. The Matriculation Examinations of the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Victoria of Manchester, Sheffield and Wales, and the Entrance or Preliminary Examination of the Universities of Scotland.

The condition prescribed by the Council in Faculties other than Arts or Pure Science is that:—

The certificate shall bear evidence that the candidate has passed in the Matriculation or Entrance standard, in the following subjects, viz.: (*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English. (*d*) A fourth subject, as defined in the regulations of the particular Examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science; Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose of matriculation or entrance.

3. Subject to the condition prescribed above (Section 2), the Council will recognise those of the examinations conducted by recognised authorities in Great Britain which are accepted by any one or more of the above-named Universities as equivalent (under prescribed conditions as to "credits" or "grades"), for purposes of Entrance or Matriculation, to an Examination named in the preceding list (Section 2). Such Examinations are:—

Bristol University: Higher School Certificate Examination; School Certificate Examination. Cambridge Local Examinations Syndicate: Higher School Certificate Examination; School Certificate Examination. Central Welsh Examination Board: Higher Certificate Examination; School Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: Higher School Certificate Examination; General School Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations; Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

4. The Council will continue to recognise certain Examinations conducted by Educational Bodies, other than those (mentioned in Section 3) whose Examinations are accepted by any one or more of the Universities of Great Britain. Recognition will not be extended under this Section to any Examination unless the Council is satisfied (*a*) that in scope and standard it is equivalent to a recognised Matriculation or Entrance Examination of a University of Great Britain, (*b*) that it fulfils the condition prescribed by the Council (Section 2), and (*c*) that the Examination has been completed at not more than two sittings. Such Examinations are:—

The College of Preceptors (England): Senior Certificate. The Educational Institute of Scotland: Preliminary Medical Certificate.

5. Subject to the prescribed condition (Section 2), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, and the Matriculation or Entrance Examinations of the National University of Ireland, the Queen's University of Belfast, the Irish Royal Colleges of Physicians and Surgeons; and also the Leaving Certificate of the Department of Education of the Irish Free State, the Senior Grade Leaving

Certificate of the Ministry of Education of Northern Ireland, and all examinations accepted by any one or more of the Universities of Great Britain or Ireland. as equivalent, for purposes of entrance or matriculation, to the above-named University Examinations.

6. Subject to the prescribed condition (Section 2), the Council will recognise all Examinations of Colonial or Foreign Universities which are accepted by any one or more of the Universities of Great Britain as equivalent, for purposes of entrance or matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

7. The Council will recognise the Final Examinations for Degrees in Arts or Science of any University of Great Britain or Ireland or of the British Dominions.

8. The registration of medical students shall be placed under the charge of the Branch Registrars.

9. Each of the Branch Registrars shall keep a register of medical students.

10. The Branch Registrar shall enter the student's name and particulars in the Students Register, and give him a certificate of such registration.

11. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of Great Britain or Ireland of which he is Registrar, blank forms of application for the registration of medical students.

12. A copy of the Medical Students Register prepared by each of the Branch Registrars shall be transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who will distribute the list to the licensing bodies, medical schools, and hospitals.

All applications for special exceptions to the foregoing regulations as to registration shall be addressed to the Registrar of the General Council, and shall be decided by authority of the Education Committee, who shall report thereon to the Council.

The Medical Schools and Colleges.

The Universities, including their Colleges and Medical Schools, and Schools of Medicine at which Medical Study may be commenced in the United Kingdom are set out seriatim in the following pages.

Medical Registration in Ireland.

Within the past few months the problem of medical registration in the Irish Free State, which had given rise to some anxiety during the past two years, has been satisfactorily settled. By agreement between the Governments of Great Britain, of the Irish Free State, and of Northern Ireland—since confirmed by legislature at Westminster and Dublin—the powers and duties of the General Council of Medical Registration and Education are to continue as heretofore in respect of qualifying bodies in the Irish Free State, and of medical practitioners qualified in the Irish Free State. Side by side with this a Medical Council has been set up in the Irish Free State with the duty of establishing and controlling a Register for the Irish Free State. Practitioners whose names are on the General Register, and persons who pass a qualifying examination in the Irish Free State, will be registered on the Irish Free State Register on payment of the prescribed fee. The Irish Free State Medical Council have, over those whose names are on the Irish Free State Register, the same disciplinary powers as are possessed by the General Council over those whose names are on the General Register. To possess the privileges of a qualified practitioner in the Irish Free State it is necessary to be registered in the Irish Free State Register.

The net result of the change in the law as regards the practitioner qualifying in the Irish Free State in the future is that: (1) If he intends to practise only in the Irish Free State he need only register in the Irish Free State Register; (2) if he intends to practise in Great Britain he will register in the General Register: and (3) if he is in doubt where he will practise he will register in both Registers. He will, as he registers in one Register, or in both Registers, put himself under the disciplinary control of the one Council or of both Councils. No practical inconvenience is caused, and practitioners qualified the Irish Free State in future will not find themselv deprived of any of the privileges or rights enjoyed their predecessors.

The Dental Board of the United Kingdom.

Anyone who is on the Medical Register is entitled practise as a dentist, although he cannot register such without degree or licence in dentistry; but is a distinct advantage to take a special dent qualification, otherwise few dental appointments general or special hospitals or dispensaries are availabl and, unless registered in the Dentists Register, dental work, under the additional Benefit Scheme the National Health Insurance Act can be undertake

Under the Dentists Act, 1921, the powers a duties of the General Medical Council under t Dentists Act, 1878, and under the Medical Act, 188 which related to the keeping of the Dentists Regist and the administration of the Dentists Acts we largely transferred to the then newly constitut Dental Board of the United Kingdom. The regi tration of dental students at the commencement their dental studies, and the right of erasure of name from the Dentists Register, remain with t Council, but the duty of inquiring into disciplina cases rests with the Board, upon whose recommend tions the Council acts.

The Dental Board consists of a chairman and members. The chairman is appointed by the Pri Council. Other members of the Board are appoint by the Minister of Health, the Scottish Board Health, the Governor-General of Northern Irelan the General Medical Council (3), Direct Vote of t qualified dentists practising in England and Wal Scotland, and Ireland (3), Direct Representatives registered dentists not being qualified dentists (2).

Registration of Dental Students.

The General Medical Council's Regulations in rega to the registration of dental students which came in force on Jan. 1st, 1923, provide that the registration dental students shall be carried on at the Gene Medical Council Office in London, in the same manr as that of medical students, and be subject to t same regulations as regards age and prelimina examinations; but in the case of dental studer professional study may commence either at a rec nised dental hospital or school, or by pupilage w a registered dental practitioner.

Candidates for a diploma in dental surgery sho produce certificates of having been engaged for least four years in professional studies, and of havi received during 24 calendar months instruction dental mechanics. It is recommended that instr tion in dental mechanics be taken at a recogni dental hospital and school. If any part of su instruction be taken by the candidate as a pu with a registered dental practitioner, the time requi to be devoted to it shall be at least twice the ti required for the corresponding instruction taken a dental school. Two years' *bona-fide* apprentices with a registered dental practitioner, after registrat as a dental student, may be counted as one of four years of professional study. When a stud can show evidence of regular pupilage in den mechanics to a registered dental practitioner, pr to the passing of the prescribed preliminary a scientific examinations, he may be allowed to anted his registration for a period not exceeding one y prior to the passing of these examinations.

The Offices.

The address of the Registrar, to whom furth communications should be addressed, is as follo The Registrar of the General Medical Coun 44, Hallam-street, Portland-place, London, W. The offices of the Dental Board are adjoining.

A memorandum on the procedure to be adop by those who desire to enter the profession of medici with notes on costs and prospects, and a sim Memorandum in regard to Dentistry, may be obtai on payment of 1*s*. each.

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS FOR THE BRITISH MEDICAL REGISTER.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M.* and *D.M.*, in Surgery, *B.Ch.* and *M.Ch.*, and diplomas in *Public Health* and *Ophthalmology*. The examinations open to men and women alike.

Only Graduates in Arts of the University are eligible the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending duates in Medicine is to take Responsions, the liminary Science Examinations mentioned below, the Final Honour School of Physiology. To in the degrees of B.M. and B.Ch. the following minations must be passed: 1. Preliminary jects: Physics and Chemistry, Zoology, and any. 2. Professional. (*a*) First Examination: jects—Organic Chemistry, unless the candidate satisfied the examiners in Part I. Chemistry in Honour School of Natural Science; Human siology, unless he has obtained a First or Second s in Animal Physiology in the Honour School of ural Science; Human Anatomy. (*b*) Second mination: Subjects—Medicine, Surgery, Midry, Pathology, Forensic Medicine with Hygiene, eria Medica and Pharmacology. The First and nd Professional examinations are held in June December. The first B.M. examination may be ed at any time after the Preliminary Scientific minations. Anatomy and Physiology must be ed at the same time—Organic Chemistry may be n separately.

t any time after passing *First B.M. Examination*, candidate can, on producing certificates, present self for examination in the subjects of Pathology, ensic Medicine with Hygiene, Materia Medica and rmacology; but cannot, unless he is already a stered medical practitioner, enter for examination edicine, Surgery and Midwifery until the eighteenth n from his matriculation, nor until a period of at t thirty-three months has elapsed from the date passing the First B.M. Examination. He must in Medicine, Surgery and Midwifery at one and same time.

efore admission to the Examinations in Pathology Bacteriology, and Materia Medica and Pharmaco-, of the *Second B.M. Examination*, the student t produce certificates of having attended courses nstruction including practical work in Pathology, teriology, Post-mortem Clerking, Pharmacology, Pharmacy, either in Oxford or in a recognised ical School. Before admission to the remainder of second B.M. Examination, he must produce a ber of other certificates, including certificates of ng acted as Clinical Clerk and Dresser, each for months in the Wards, of instruction in Midwifery of attendance on Labours, of instruction in ctious Diseases and in Ophthalmology, of proficy in Vaccination and in the administration of sthetics, and of three academic years of hospital tice.

he degree of Bachelor of Surgery (B.Ch.) is granted that of B.M. after passing the above examinations.

he degree of Doctor of Medicine (D.M.) is ted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by the examiners for the B.M. degree whose subjects are dealt with therein and by Professors in the Faculty of Medicine. The degree of Master of Surgery (M.Ch.) is granted after examination to Bachelors of Surgery who have entered upon their twenty-first term, and who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

The examinations for the Diploma in Public Health in two parts are held in Trinity and Michaelmas terms; that for the Diploma in Ophthalmology is held annually in July. (See p. 421.)

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects, Animal Physiology, Botany, Zoology. A George Herbert Hunt Travelling Scholarship of the value of about £100 is awarded every second year to enable a Bachelor of Medicine to undertake three months' study abroad. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907). is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year on the nomination of the Regius Professor of Medicine. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships varies, according to the Candidate's need, between £30 and £100 a year; the exhibitions vary in value from £30 to £100 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1923; from the Regius Professor of Medicine; from the Professors in the departments of medical science; and from the Dean of the Medical School, Oxford.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—225 beds. Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) clinical lectures by the Litchfield

Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. A post-graduate course is held in the hospital in the autumn of each year.

UNIVERSITY OF CAMBRIDGE.

There are two degrees in Medicine, *M.B.* and *M.D.*, two in Surgery, *B.Chir.* and *M.Chir.*, and Diplomas in *Public Health and Hygiene*, *Tropical Medicine* and *Hygiene*, and *Medical Radiology and Electrology*. Increased facilities have been given to women students at Girton and Newnham, who are admitted to the *M.B.* Examinations.

The student must enter a College, or become a non-collegiate student, and keep nine terms (three years) by residence. He must pass the Previous Examination of the University before he comes into residence or therefrom obtain exemption, particulars of which may be obtained from the Registrar. He may then devote himself to medical study in the University. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing the Examinations for the Ordinary B.A. degree, or an Honours degree by passing a Tripos Examination. The Natural Sciences Tripos is taken most frequently by medical students, as some of the subjects are practically the same as those for the First and Second M.B. examinations.

For the degree of Bachelor of Medicine (*M.B.*) five calendar years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the *First and Second M.B. examinations*. Hospital practice may be attended in Cambridge, but until the student has completed the course for the *Third part of the Second M.B.* it cannot count towards the two and a half years of hospital practice required before admission to the first part of the Third M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *First* includes (1) General and Inorganic Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *Second* is divided into three parts—viz. (1) Organic Chemistry, (2) Human Anatomy and Physiology, and (3) Pharmacology and General Pathology. The *Third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic. Candidates who have passed both parts of the Third M.B. examination are admitted to the registrable degree of Bachelor of Surgery (B.Chir.) without separate examination and without keeping an Act.

The degree of Doctor of Medicine (M.D.) may taken three years after that of M.B. or four years a that of M.A. The candidate is required to prod certificates of having been engaged in Medical St for five calendar years, and if an M.A. to pass the s examinations as are required for the degree of M An Act has to be kept, consisting of an original Th with *viva voce* examination; and a short extemp essay has to be written on a topic taken from general subject of his thesis, whether it be Physiol Pathology, Pharmacology, the Practice of Medici State Medicine, or the History of Medicine.

Candidates for the Degree of Master of Surg (M.Chir.) who are M.A.'s may be admitted to examination after they have become legally quali under the *Medical Acts* to practise surgery. Oth may be admitted to the examination when two ye at least have elapsed after they have completed that is required of candidates for the Degree B.Chir. He is required to pass an examination Principles and Practice of Surgery, Surgical Anato and Surgical Operations, and Pathology, and write an extempore essay on a Surgical Subject.

Diplomas are granted in Public Health, Hygiene, in Tropical Medicine and Hygiene, and Medical Radiology and Electrology. Candidates m hold a recognised medical qualification. (See p. 4

Scholarships and Prizes.—Medical studies endowed by the numerous Natural Science schol ships at the various colleges, information about wh can be obtained from the respective Tutors. Th are Natural Science scholarships at most of colleges and prizes in the ancillary medical subje Some of these are entrance scholarships; some n be gained by students already in residence, and wh suitable candidates are not forthcoming among st students the emoluments may be allotted to memb of other colleges. A valuable scholarship institu on behalf of Medicine is the Tancred Studentship Physic, tenable at Gonville and Caius College. T successful candidate must enter at the college wit a month or remove there if he be a member of a other college. Students are required to take degree of M.B. as soon as they are of sufficie standing but may hold the Studentship for a furt three years. Thus a student elected previous admission to college can draw the emolument, annual value of which is about £90, for eight yea Full particulars can be obtained from Mr. E. Gurdon, 28, Lincoln's Inn-fields, London. Amo other scholarships and prizes may be mentioned Balfour Studentship, for research in Biology, of value of £300 a year for three years, not restric to members of the University; the Frank Sm Studentship and Prizes for Botany and Zoology, a the Shuttleworth Studentship for Zoology or Phy ology tenable at Gonville and Caius College. The University Prize in Medicine, the Raymond Hor Smith Prize, is awarded to that candidate for the deg of M.D. who presents the best thesis for the deg during the academical year, provided that he has tak honours in a Tripos Examination.

An abstract of the Regulations and Schedules of range of the examinations in Chemistry, Mechan Physics, Biology, Pharmacology, and General Pa ology may be obtained upon application to Registrary, The Registry, Cambridge.

ADDENBROOKE'S HOSPITAL.—190 beds. Clini Lectures in Medicine and Surgery, in connexion w Cambridge University Medical School, are given this hospital twice a week during the academi year; and practical instruction in Medicine a Surgery is given in the wards and out-patien rooms by the physicians and surgeons daily dur the term time and vacations. The fee for pupils is 3 guineas a term, 9 guineas a year, 12 guin perpetual. Further information may be obtained fr Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London in 1900 was reconstituted ler the Act of Parliament, 1898, and became a ching as well as an examining body. Under the elopments upon the Internal side all the metro- tan medical schools became constituent colleges, le Clinical Units have been established at St. tholomew's, the London, St. Mary's, St. Thomas's, versity College Hospital, and the Royal Free spital.

nternal and External Students.—All the examina- is of this University are open to men and women e. Matriculated students of the University may either internal or external. Internal students of University are students who have matriculated he University and who are pursuing a course of ly approved by the University, either (*a*) under the ct control of the University or a committee ointed thereby; or (*b*) under one or more of the ointed or recognised teachers of the University. tres for preliminary and intermediate medical lies have been established by the University at versity and King's Colleges.

NIVERSITY COLLEGE.—University College has been stituted a University centre for the teaching of ical sciences. The College Faculty of Medical nces comprises the Departments of Physics, mistry, Botany, and Zoology (the Preliminary ical Sciences); also the Departments of Anatomy, ology, Physiology, Biochemistry, and Pharmaco- (the Intermediate Medical Sciences), and the artment of Hygiene and Public Health. Research k is undertaken in all departments. The comple- of the Institute of Medical Sciences, which the rosity of the Rockefeller Foundation made ible, provides exceptional facilities for research post-graduate study in anatomy, physiology, and rmacology. In particular might be specified the ortunities for investigation in human and com- tive embryology and neurology, in histology, ology, anthropology, biochemistry, and experi- tal physiology and experimental embryology. ngements exist for the close correlation of work he Institute with University College Hospital Medical School. Women students are admitted.

holarships and Prizes.—The first four items on present list require a complete intermediate course niversity College. The money value and subjects xaminations are as follows: (*a*) The Bucknill larship, 160 guineas; (*b*) and (*c*) two Entrance ibitions, 55 guineas each, Chemistry, Physics, ny, and Zoology; (*d*) Entrance Scholarship, a year for three years; (*e*) Cluff Memorial Prize, biennially, Anatomy, Physiology, Pharmacology, Chemistry; (*f*) Schafer Prize in Physiology, £18 nially; (*g*) Sharpey Physiological Scholarship, , Biological Sciences; (*h*) Morris Bursary for sons eceased professional men, by nomination, tenable wo years, £16 a year; and (*i*) five Gold and five r Medals awarded annually in various depart- ts. For further information apply to the Dean e Medical Faculty, University College, W.C.

ING'S COLLEGE.—The Medical Faculty at this ge gives instruction in the subjects of Medical ce for the Preliminary and Intermediate Exam- ons in Medicine and Surgery, and Dental Surgery, e University of London and of other Universities examining bodies, to students entering the ge directly, and also to students of the following hospital schools which prepare only for the examinations—viz., King's College Hospital, minster Hospital, St. George's Hospital, and ing Cross Hospital. The Faculty is open to men and women.

holarships and Prizes.—Two Warneford Entrance larships of £30 each for four years. Examination pril, subjects selected from Divinity, Classics, ce. Sambrooke Scholarship of £30 for three . Examination in April, subjects selected from Classics, Science. Worsley Scholarships: £100 in five annual instalments of £20. *At the end of the First Year* of study, the Rabbeth Scholarships (£30 and £15), the Carter Gold Medal and Prize in Botany, and the Hare Prize in Zoology are open for competition. *At the end of the Second Year*, the Second Year's Scholarship (£20) is open for competition. *At the end of the Third Year*, the Hughes Prize in Anatomy, the Huxley Prize in Physiology, the Inchley Prize in Pharmacology, and the Jelf Medal are open for competition. The Layton and the Berridge Research Studentships (£150 per annum each), the Daniell Scholarship in Chemistry (£40), Warneford Prizes (£25 and £15), Leathes Prize, Barry Prize, &c., are also open to Students of this Faculty. The majority of the Scholarships and Prizes are open to Regular Students only. For further information apply to the Dean of the Medical Faculty.

Medical students of the University of London, who are pursuing their medical curriculum in the metropolis will proceed to one of the recognised medical schools connected with the University. At four of these schools the preliminary studies will be taken at King's College, while at the other schools the whole curriculum can be taken out in connexion with the selected hospital. These hospitals are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. Various schools and hospitals are also recognised as schools of the University in special departments, and students may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.

The Faculty of Medicine of the University grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*) and the degree of B.Pharm. (*Bachelor of Pharmacy*); the two higher degrees being open only to candidates holding the M.B., B.S degrees of the University. The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Thursday following the second Monday in March and on the Thursday following the first Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital; (14) The conduct of at least 20 Labours; (15) Antenatal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work; (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. Bachelors of Medicine who graduated before May, 1904, may obtain the B.S. by passing the Surgical part of the M.B., B.S.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis for approval and may be exempted from a part or from the whole of the written examination.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology, and Rhinology. A thesis may be submitted as for M.D.

Bachelor of Pharmacy.—The course extends over three years.

Full details of the prescribed curricula can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electrotherapeutics and X Ray work. Whole-time Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, are provided with room and board, and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear, and a house surgeon for orthopædic surgery are appointed every six months and are provided with rooms and board and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for a year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential College is attached to the hospital.

There are quarters for the resident staff, casualty medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry. *The Medical College Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is complete. A new block in Gilston street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Special Classes for the Primary and Final F.R.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. Facilities for research work are afforded in the Clinical Units and Laboratories of pathological and other departments. *A Vacation Post-graduate Course*, adapted to general practitioners, is given annually.

Scholarships given in aid of Medical Study.—There are five of the Scholarships and the Exhibition—namely (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100; (*c*) Entrance

[1] Of these schools that of the Royal Free Hospital is restricted for women; University College admits men and women to the whole course, the number of women being limited; King's College admits men and women to the intermediate subjects, the remainder admit men only.

olarship in Arts, £100; (*d*) Jeaffreson Exhibition, ; and (*e*) Shuter Scholarship, £50—a full or versity course at St. Bartholomew's Hospital is iired. The awards of (*a*) and (*b*) are made after mination in selections from the subjects of mistry, Physics, Zoology, Botany, Physiology, tomy, and Pathology; (*c*) and (*d*) are awarded r examination in Mathematics, Latin or ek or French or German, a second language or mistry or Physics; (*e*) is awarded after competitive mination among Cambridge Graduates in Anatomy Physiology. The more important of the other olarships and prizes are as follows:—Four Junior olarships—(*f*) No. 1, £30, Anatomy and Physiology; No. 2, £20, Anatomy and Physiology; (*h*) No. 3, Chemistry, Physics, and Biology; (*i*) No. 4, £15, mistry, Physics, and Biology; (*j*) Senior Scholar-, £50, Anatomy, Physiology, and Chemistry; (*k*) kes Scholarship, £30 and medal, Clinical Medicine; nd (*m*) two Brackenbury Scholarships, £39 each, in Medicine and one in Surgery; (*n*) Sir G. rows Prize, 10 guineas, Pathology; (*o*) Skynner e, 13 guineas, Regional and Morbid Anatomy; Matthews Duncan Medal and Prize, £20, Midwifery Gynæcology; (*q*) Luther Holden Research olarship in Surgery, awarded by election, £105; Lawrence Research Scholarship and Gold Medal Pathology, awarded by election, £115; and Baly Scholarship in Clinical Medicine, £75, rded by examination.

he recreation ground of 10 acres is at Winchmore for the use of the members of the Students' on, which all students are expected to join. The dents' Union contains a large reading and smoking n, a committee and writing room, luncheon and ng hall, and a miniature rifle range.

nformation may be obtained on application to the n of the Medical College: Dr. T. W. Shore. The rden of the Residential College is Mr. R. M. Vick.

HARING CROSS HOSPITAL.—The Hospital, to which School is attached, contains 300 beds. There special departments for Mental Diseases, Mid-ry, Diseases of Women, of Children, of the Skin, , Throat, Nose, and Teeth, for Orthopædic Cases, Ray work, and for Electrical Treatment.

n the Medical School Demonstratorships and istant Demonstratorships are open to students the School. Six House Physicians, six House geons, two Obstetric and Gynæcological House geons, and two House Surgeons to the Special artments are appointed annually. The large portion of resident appointments to the number students makes it probable that a student of inary ability will be able to obtain one of these ointments.

he following appointments are open to students r they have held resident appointments: Resident lical Officer, at a salary of £400 per annum; istrar to the Medical, Surgical, Obstetrical and , Nose, and Throat Departments, at £150 per um.

y an agreement with the University of London School sends its Primary and Intermediate dents to receive their lectures and practical work King's College, which is situated within four minutes' k.

inal studies are taken in the school and hospital, re systematic lectures, demonstrations, and rial classes are arranged to cover all the subjects essary for qualifying examinations. Departments also available for other final subjects of Materia lica and Operative Surgery.

n Institute of Pathology with a whole-time staff scientific workers and fully equipped laboratories been established. Students receive their training Preventive Medicine, Pathology, Bacteriology, and chemistry here, and are encouraged to undertake earch. Special facilities are available for post-duate research and study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Special demonstrations are arranged for Post-graduates.

One Epsom School Scholarship, two Oxford and Cambridge Scholarships, and one Scholarship in Anatomy and Physiology open to students of King's College, are offered for competition each year. In addition there are a number of Exhibitions.

The Museum contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, the Cuthbert Lockyer Collection.

The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, in a Students' Club. The Club, which is under the control of a committee of students, provides needful athletic recreation, and includes also a medical society.

Further information may be obtained on application to the Dean, Dr. F. H. Young.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. There are all the usual special clinical departments. One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds. Children's beds are placed in the women's wards. There are two ophthalmic wards.

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum; Medical Registrarship at £200 per annum, Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the posts (3) of Junior Anæsthetists, each at £30.

Entrance Scholarships and Endowed Prizes of a total value of £700 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at that College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Scholarships and Prizes.—At this school five entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively; (*c*) and (*d*) two University Entrance Scholarships, 90 guineas and £70 respectively; (*e*) Devitt-Pendlebury Scholarship, £50, Anatomy and Physiology, except in the case of (*c*), subject of examination for which is General Pathology.

This year, in addition to these Scholarships, Exhibitions, each of the value of £40 and up to six in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*f*) Allingham Scholarship in Surgery for Students qualified not more than two years, £85; (*g*) and (*h*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing; (*i*) H. C. Johnson Memorial Prize, £19, Practical Anatomy; (*j*) Pollock Prize, £23, Physiology, Physiological Chemistry, and Histology; (*k*) Clarke Prize, £5; (*l*) Thompson Medal, £9, Clinical Reports; (*m*) Brodie Prize, £8, Clinical Reports; (*n*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*o*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications.

The St. George's Hospital Club, with smoking- and luncheon-rooms is on the hospital premises and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Further information may be obtained from the Dean of the Medical School, Dr. A. Feiling.

GUY'S HOSPITAL.—This hospital contains 642 beds. The whole of the medical school has been rebuilt within recent years. It provides ample accommodation, with modern equipment, for all the non-clinical subjects of the medical curriculum.

The following special departments are attached to the hospital: Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anæsthetics, dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children). Dresserships and clerkships in the various special departments are held by students in turn.

There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

House physicians, house surgeons, out-patient officers, assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology, laryngology, and genito-urinary diseases, house physicians in the department for diseases of children, and clinical assistants are appointed from among recently qualified students according to merit.

Scholarships.—Six entrance scholarships are awarded annually as follows:—(*a*) one War Memorial scholarship, of the value of £200, to be awarded alternately in Arts and Science (next award, June or July, 1930 in Science); (*b*) one Open Arts Scholarship of £100 for students under 19 years of age; candidates may offer themselves in either of the following groups: (1) English and any two of the following—viz., Latin, Greek, or Mathematics; (2) English and any two of the following—viz., French, German, and Mathematics; (*c*) one Open Junior Science scholarship for students under 20 years, £100; subjects, any three of the following: Inorganic Chemistry, Physics, Biology, and Mathematics; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in June or July, to candidates who have attended the Preliminary Science Classes at this School; (*e*) two open Senior Science scholarships: (1) a War Memorial scholarship of the value of £100, awarded annually in September; (2) an open scholarship of the value of £80, awarded annually in September, for students who have completed the curriculum for, or passed the examinations in, Anatomy and Physiology for a medical degree in any University of the British Empire, and who, during the nine months immediately preceding the Scholarship examination, have not entered as students in any Metropolitan Medical School other than Guy's; subjects, any two of the following: Anatomy, Physiology, Organic Chemistry and Pharmacology, General Pathology.

Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 15 minutes from the hospital.

Further information can be obtained from the Dean of the Medical School, Prof. T. B. Johnston.

KING'S COLLEGE HOSPITAL.—The final subjects the curriculum are taught at the Medical School King's College Hospital, which is situated at Denm Hill, S.E. 5.

The hospital has 400 beds, and provision ultimately be made for 600. There are spec departments for Bacteriology, Children, Clinical Pat logy, Dermatology, Gynæcology and Obstetri Laryngology, Massage, Neurology, Odontology, O thalmology, Orthopædics, Otology, Physical Tre ment, Psychological Medicine, Radiology, Rhinolo and Urology, each in charge of a specialist and staff. Clinics are also held in applied pharmacolo cardiology, and medical chemistry.

Appointments.—The appointments open to stude are those of clinical assistant to the special dep ments; medical, surgical, obstetric, and patholog tutorships; resident casualty officers, house physici and house surgeons; resident anæsthetist; resid radiologist; bacteriologist; clinical pathologi pathological, medical, surgical, and obstetrical re trarships. Sixteen resident medical and surg officers are appointed half-yearly.

Scholarships and Registrarships (those in connex with King's College have already been enumerated Scholarships of the total value of £1095 are awar annually. These include (*a*) Medical Entra Scholarships—Science, £50; Anatomy and Phy logy, £50; Pathology, £75; (*b*) two Burney Entrance Scholarships, £80 each, open to student Oxford and Cambridge on the recommendation of Regius Professors; (*c*) two Raymond Gooch Scho ships, £120 each, open to students of British Uni sities on certain conditions; (*d*) an Epsom Col Scholarship, value £50 at least, offered annually a student of Epsom College who has taken the part of the courses for Medical Degrees at the Uni sities of Oxford, Cambridge, or London; (*e*) a Sea Scholarship, £50 a year for a period not excee five years, restricted to the sons of poor clergy of the Church of England; (*f*) Senior Scholar (Clinical Studies), £40. The holders of the Warne and Sambrooke Scholarships awarded by Ki College are required to take the subjects of preliminary and intermediate examinations at Ki College, and the final subjects at King's Co Hospital. Three Sambrooke Registrarships, ope matriculated stidents who have filled certain app ments in hospital.

Prizes.—Tanner Prize, £10, Obstetrics and Dise of Women; Todd Prize, £4 4*s.* and medal, Cli Medicine; Burridge Prize, £4 4*s.*, Forensic Medic Jocelyn Almond Prize, £5 5*s.*, Diseases of Child Wallis Prize, £10, History of Dentistry; 13 Prizes, £3 each.

The King's College Hospital Clubs and Soci Union consists of the Listerian and Musical Socie the Students' Common Rooms, and the va athletic and sports clubs. The athletic ground, six acres in extent, is on Dog Kennel Hill, abou minutes' walk from the hospital. There are Tennis Courts in the grounds of the Hospital of "The Platanes"—a hall of residence for stu belonging to the hospital.

The Calendar of the School will be sent on ap tion to either of the following: Dr. H. Willou Lyle, Dean; Mr. S. C. Ranner, Secretary of Medical School.

LONDON HOSPITAL.—The hospital, with its Me College and Dental School, is situated in Mile road, and contains 837 beds. There are sp departments for diseases of the Eye, Ear, Nose Throat, Skin, Teeth, and Pediatric, Orthop Venereal, Radiological, Electro- and Physico-t peutical and Inoculation Departments.

To each medical and surgical firm throughou hospital there is attached a First Assistant, w responsible for instructing the clerks or dress

firm in elementary medicine and surgery, and o assists the honorary members of the firm in preparation of their demonstrations. In the partment of Obstetrics and Gynæcology there are o assistants and two resident accoucheurs. Special rses of lectures and demonstrations are arranged Medicine and Surgery and their ancillary subjects. portunities for research are provided under the ervision of the staff.

Owing to the large number of patients more appointnts are open to students before and after qualifican than at any other hospital. Holders of resident ointments have free board. Special classes are d for the examinations of the University of London, the Fellowship of the Royal College of Surgeons, the Membership of the Royal College of Physicians, l for other higher examinations. Special entries for dical and surgical practice can be made.

A Clinical Unit in Medicine, under the charge of whole-time director, provides for the more elaborate thods of diagnosis and treatment, and takes a ding part in the initiation and coördination of dical research. The director has an assistant ector, two assistants, and two house physicians.

Scholarships and Prizes.—The following is a list of Scholarships and Prizes :—Price Scholarship £100, l one Entrance Scholarship of £50, subjects of First dical Examination at the University of London ; som College Scholarship, free education, subjects First Medical Examination as above; Price holarship, open to students of Oxford and mbridge Universities, (1) £100, Pathology ; (2) £75, man Anatomy and Physiology ; Buxton Prize, £40, jects of Anatomy and Physiology ; three Prizes Clinical Work, £20 each, Medicine, Surgery, and stetrics and Gynæcology ; Sutton Prize, £20, thology ; Duckworth Nelson Prize, biennial, £10, actical Medicine, and Surgery ; Letheby Prizes (2), 5, Chemistry and Chemical Pathology ; four essers' Prizes, amounting to £20, zeal, efficiency, l knowledge of Elementary Clinical Surgery ; tchinson Prize, triennial, £60, Clinical Surgery ; ves Prize, £15, Clinical Surgery ; two Practical atomy Prizes, £6 and £4 respectively ; Andrew rk Prize, £14, Clinical Medicine and Pathology ; A. M. Ross (Prox. Acc.) Prize, £10 10s., Clinical dicine and Pathology ; James Anderson Prizes , £20, Elementary Clinical Medicine ; Arnold ompson Prize, £15, Diseases of Children ; K. E. D. yne Prize, Research Scholarship, £20, Pathology ; d Liddle Prize, triennial, £120.

Medical Research Funds.—Funds to the value of over),000 permit of financial assistance being given to dents and graduates engaged in Medical Research. Two Residential Hostels are provided for students. e recent additions to the hospital and college ildings include the Dunn Clinical Laboratories, e Bearsted Clinical Theatre, the Bernhard Baron stitute of Pathology, and a hostel for 40 resident dical officers. The Union Athletic Ground, 13 acres, within easy reach of the hospital.

Dean : Prof. William Wright.

ST. MARY'S HOSPITAL.—The Hospital and Medical hool have on one side a poor district of 500,000 rsons, and on the other side the residential districts Kensington and Bayswater. The hospital contains) beds and structural additions during the past ar have added two new operating theatres. By cheme of affiliation, for teaching purposes, of certain ighbouring hospitals, the teaching facilities extend er 1000 beds. The Medical School provides comte courses of instruction, and students can join once on passing a Preliminary Examination in ts. Terms begin in October, January, and April. Clinical Units in Medicine and Surgery were estabned in 1920. Lying-in beds have recently been ded, and, in addition to this, arrangements have en made by which all students take out a short course of instruction in Practical Midwifery at Queen Charlotte's Hospital without additional fee.

Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright. Certain Research Scholarships of £200 each are awarded annually to students working in the departments of the institute ; and research beds have been instituted. Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the Medical School, including ten salaried posts with salaries varying from £200 to £750 per annum.

Entrance Scholarships.—Two Entrance Scholarships of the value of £210 each are awarded annually, by nomination in July, the Geraldine Harmsworth Scholarship, £200, and one or more University Scholarships of £200 are awarded in July.

The Athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains. A large pavilion has recently been added.

For further information apply to the Dean of the Medical School.

MIDDLESEX HOSPITAL.—The hospital contains over 450 beds, with special wards for Cancer, Maternity and Gynæcological and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin ; Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electrotherapeutic department. The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electrotherapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

All appointments are made without fee of any kind, and the following are appointed at intervals annually : six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, four resident anæsthetists, and four resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. Nine registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

The Medical School, which includes the Bland-Sutton Institute of Pathology, the Courtauld Institute of Biochemistry, and the Cancer Research Laboratories is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 Professors, 32 recognised Teachers, 10 Demonstrators, 4 tutors. The Bland-Sutton Institute of Pathology is completely equipped for routine hospital investigations, teaching and research work, and contains a lecture theatre, large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility.

Other features of interest are : the course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics ; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone, Prof. J. McIntosh, and Prof. W. B.

Tuck. A primary F.R.C.S. course is held twice yearly, and special classes to prepare students for the Intermediate Examinations of the Universities.

Scholarships and Prizes.—Two Entrance Scholarships, value £100 each, and two University Scholarships, value £90 and £60, are awarded annually in September. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship is awarded annually on the nomination of the Headmaster of Epsom College. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5*s.*; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas. There are also numerous class prizes.

The Amalgamated Students' Club includes the following: Medical Society, Common Room Society, Musical Society, cricket club, football clubs, athletic club, rowing club, chess club, lawn tennis club, and hockey club. There are a restaurant and gymnasium in the school buildings, and large athletic grounds at N. Wembley, with new pavilion.

For further particulars apply to the Dean or the Secretary of the Medical School.

ST. THOMAS'S HOSPITAL.—This Hospital contains 644 beds. There are special departments for the treatment of women, children, diseases of the eye, ear, nose and throat, skin, teeth, and for orthopædics. Nervous and mental diseases are treated in special departments. An electrocardiograph has been installed for the investigation of diseases of the heart. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for Radiology, Electrotherapy, Phototherapy, Massage and Remedial Physical Exercises are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day, except Saturdays, at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. A Clinical Unit in Medicine has been established.

All appointments in the hospital are open to students without extra fee. Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward and district, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists.

The arrangements are made to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments.—A Resident Assistant Physician and a Resident Assistant Surgeon, salary £225 each per annum, and a Resident Anæsthetist, salary £200 per annum, are appointed annually. Two Hospital Registrars, Medical and Surgical, at an annual salary of £250 each are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. A Pathological Registrar to the Department of Obstetrics and Gynæcology (at an annu salary of £250), an Ophthalmic Registrar (at an annu salary of £50), and an Orthopædic Registrar (unpai are appointed yearly. Two Senior Resident Casual Officers (Medical and Surgical) are appointed year Eight Resident Casualty Officers and Anæstheti are appointed every six months. Seven House Ph sicians (including two Obstetric House Physicia and one House Physician to the Department of Disea of Children), nine House Surgeons (including t Ophthalmic House Surgeons, one Orthopædic Ho Surgeon, and two House Surgeons to the Ear, Nose a Throat Department) are appointed every six mont Clinical Assistants in the Special Departments appointed every three months, and hold office six months if recommended for re-election. Th are three Assistants in the Department of Patholog the Senior receives £600 a year, and the two Juni £450 each.

Scholarships and Prizes.—At this school there five Entrance Scholarships—namely, two in A equivalent to the tuition fees for the first year study; two in Natural Science, of the value of £ and £60 respectively; and the University Scholars of £100 in any two of the following: Anaton Physiology, Pathology, Chemistry. The value of entrance scholarships must be taken out in tuition f The money value and subjects of examination of remainder are as follows: (*a*) William Tite Scholars for second-year students, £25; (*b*) and (*c*) Musgr Scholarship or (alternately) Peacock Scholarship, e for third-year students and tenable for two years, each; (*d*) Mead Medal, Medicine, Pathology Hygiene; (*e*) Wainwright Prize, Medicine; (*f*) To Prize, Medicine; (*g*) Cheselden Medal, Surgery Anatomy; (*h*) Clutton Memorial Medal in Clin Surgery, biennial; (*i*) Beaney Scholarship, £ biennially, Surgery and Surgical Patholo y; Solly Medal and Prize, biennial, Reports of Cas (*k*) Sutton Sams Prize, biennial, Report of Cas (*l*) Bristowe Medal, Pathology and Morbid Anaton (*m*) Hadden Prize, Pathology and Morbid Anaton (*n*) Grainger Testimonial Prize, £31 10*s.*, Anatomy Physiology; (*o*) Louis Jenner Research Scholars tenable for two years, £60 annually, Patholo (*p*) School Council Research Scholarship, £250 annum, tenable for two years; (*q*) John and Tem Research Fellowship, tenable for two years, £ Children.

St. Thomas's House, the New Students' C recently opened, comprises spacious dining-, smoki and reading-rooms, and accommodation for s 60 resident students. There is no occasion for stud to leave the hospital premises during working ho

Further information may be obtained from Medical Secretary of the School, St. Thomas's Hosp

---

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCH —The final subjects in the curriculum are taugh the Medical School of the hospital, which has 526 b including 74 in the new obstetric hospital. The co of instruction is suitable for the examinations at Universities of Oxford, Cambridge, Durham, and o British Universities, and for the medical educa required by the Examining Board in England and Society of Apothecaries. Clinical Units in Medic Surgery, and Obstetrics and Gynæcology are no operation. The whole-time Directors of the Units concerned with the organisation of the teaching ge ally, but the honorary staff are responsible for largest share of the teaching in the wards and patient Department of the hospital. The departm of otology, rhinology, and laryngology (the Royal Hospital) has been provided with a separate buil in Hunter-street, adjacent to the obstetric hosp It contains 39 beds, including eight private ward patients of limited means. The hospital is equi with all modern appliances for investigation. new buildings of the Obstetric Hospital of 74 (rendered possible by the Rockefeller Benefact the new Residents' House (with accommodatio

esidents and students), the extension to the Nurses' ne, and new research laboratories for the Medical ool are now finished and in full occupation. Twelve nen students are admitted annually.

hose who are desirous of carrying out original arch in Pathology, including Morbid Anatomy, teriology, Experimental Pathology, and Chemical hology, are admitted to work in the laboraes of the school by the Professor of Pathology, under certain conditions can receive grants from Charles Graham Medical Research Fund. A ial course of instruction is given in conjunction University College for preparation for the examions for Diplomas in Public Health of the various versities and examining bodies. In the Dental ool in Great Portland-street, formerly known the National Dental Hospital, there is afforded opportunity for attending lectures and practical ruction in diseases of the mouth and teeth.

ppointments.—Clerkships and dresserships to the sicians, surgeons, anæsthetist, and pathologist are tted amongst the students of the hospital. ernity students are appointed each month and le in the Students' House connected with the ical School and Hospital. Fourteen house sicians, six house surgeons, ten obstetric assistants, house surgeons to the Royal Ear Hospital (of the l number of resident officers not more than three be held by women students at any one time) are cted annually by examination from among the or students who have a medical qualification. house officers reside free in the hospital. In ition to these posts there are certain special ointments which are vacant from time to time are filled by senior students of the hospital: ident Medical Officer, Surgical Registrar, Medical istrar, Obstetric Registrar, Harker-Smith Cancer istrar, Ophthalmic Registrar, Registrar to the al Ear Hospital, Casualty Medical Officer and a ualty Surgical Officer, Assistants in Ear and oat, Skin and Venereal Diseases Departments, House Anæsthetist.

cholarships and Prizes (those in connexion University College have already been enumed).—At this School the first two Scholars (*a*) and (*b*) entitle the holder to a complete rse at University College and University College pital Medical School; the second two (*c*) and entitle to a final course at the Medical School. money value and subjects of examination are as ows:—(*a*) Entrance Scholarship, Bucknill, 135 neas, Chemistry, Physics, Botany, and Zoology; Epsom Free Medical Scholarship, subjects of liminary Scientific Examination and Nomination Epsom College; (*c*) and (*d*) two Goldsmid Entrance ibitions 112 guineas each, Anatomy or Physiology, General Pathology; (*e*) Graham Scholarship in hology, £300 per annum for two years, awarded the Senate of the University of London; (*f*) inson Morley Scholarship, tenable for three years, per annum, Surgery; (*g*) Atchison Scholarship, able for two years, £55 per annum, General ficiency in Medical Studies; (*h*) Magrath Clinical olarship, about £150, Clinical Cases; (*i*) Percival yn Scholarship, about £75, Surgery; (*j*) Filliter ibition, £30, Pathology; (*k*) Erichsen Prize, £10 10*s.*, ctical Surgery; (*l*) two Senior and two Junior lowes Clinical Medals for Clinical Medicine; (*m*) two ton Gold Medals for Clinical Surgery; (*n*) Alexander ice Gold Medal for Pathology and Surgery; and Tuke Silver and Bronze Medals for Pathology. Radcliffe Crocker Travelling Scholarship for matology. (*q*) Leslie Pearce Gould Travelling olarship for Surgery.

he *Museum of Pathological Anatomy* is open for dy daily, and microscopic sections of most of the cimens have been prepared and are available for use of students on application to the Curator. Anatomical Museum of the University of London, iversity College, is open to all students of University lege Hospital and Medical School on the recommdation of the School Committee. The Medical Library, open daily to every student of the School, contains about 20,000 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the Medical School are required to become members. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School, and the Athletic Ground at Perivale.

University College Hall, Ealing, is recognised by the authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge.

Full information can be obtained from the Dean of the School.

WESTMINSTER HOSPITAL.—The Hospital contains 240 beds. By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore. There are separate departments for Diseases of the Eye, Skin, Teeth, Ear, Nose, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, for Venereal Diseases, and for Massage, Electrical and Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments are open to students.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £75 each. Summer Session: Two Scholarships in Anatomy and Physiology, £75 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Reports on Cases; Clinical Surgery Prize, £5, Reports on Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, £40, Chemistry; Rabbeth Scholarships open to First-year Students, one of £30 and one of £15; Class Examinations in the Preliminary Scientific Course.

The Athletic Grounds are situated in Tooting and are reached in 20 minutes from the hospital.

Inquiries should be addressed to the Dean of the Medical School.

ROYAL FREE HOSPITAL, LONDON: SCHOOL OF MEDICINE FOR WOMEN.—The Royal Free Hospital contains 268 beds. The Hospital also has large Casualty and Out-patient Departments, and Departments for Special Diseases. A new and specially equipped block contains the Obstetrical and Gynæcological Unit, which controls 68 beds. A Children's Department, including 18 cots, an Orthopædic Department, and a Light Department have recently been added to the Hospital. Maternity Districts are attached to the Unit operating in the Gray's Inn-road and Essex-road areas. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, South London Hospital, and Royal London Ophthalmic Hospital.

A Clinical Unit in Obstetrics has been established. Courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the Royal London Dental Hospital, Leicester-square.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 9 and 16, Brunswick-square, 5, Mecklenburgh-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants, clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

Scholarships and Prizes.—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years. (*d*) Bostock Scholarship, tenable for two or four years, £90 (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1931, £16. (*i*) John Byron Bursary, tenable for two years, for students already in the School requiring assistance for the prosecution of their medical studies; application to the Secretary by March 31st next, £20. (*k*) Helen Prideaux Prize and Julia Ann H. Cock Prize, awarded alternately every year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £60 each. (*l*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1929. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s*. a year, awarded in alternate years; next award in July, 1929. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1928. (*p*) Alfred Langton Scholarships, tenable two years, one awarded annually, £50 a year. (*q*) School Jubilee Bursary, tenable for three years, £50 a year. (*r*) Flora Murray Bursary, awarded every year to a fifth-year student, £50. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clini Obstetrics, value £8, for proficiency in senior subje respectively. Two Evans Prizes of £2 2*s*. and £1 1*s*. given each year on the results of the class examinat in Midwifery. The Evans Prize for Operative M wifery, value £5 5*s*.; the Dr. Helen Webb Prize Children's Diseases, £5 5*s*.; the Mary Swann Prize Gynæcology, £5 5*s*.; the Edward Hanson Prize Physiology, £2 10*s*.; and the Edith Pechey Phip Prize in Pharmacology, value £3 3*s*., are awar annually.

The Students' Union arranges the social, athle and other clubs and societies. The School spo ground, consisting of 7½ acres of freehold land, situated at Sudbury (easily reached from Eus Station).

Inquiries may be addressed to the Warden Secretary of the Medical School, 8, Hunter-str London, W.C.

UNIVERSITY OF DURHAM.

The University of Durham grants degrees Bachelor of Medicine, Bachelor of Surgery, Doc of Medicine, Master of Surgery, Doctor of Surge Bachelor of Hygiene, Doctor of Hygiene, Bach of Dental Surgery and Master of Dental Surge the Diploma in Public Health, Diploma in Psychia and a Licence in Dental Surgery.

For the degrees of *Bachelor of Medicine* and *Bach of Surgery* there are four professional examinatio The subjects of the First Examination are—Elem tary Biology and Organic Chemistry. The subj of the Second Examination are—Anatomy Physiology. The subjects of the Third Exami tion are—Materia Medica, Pharmacology, gen principles of Therapeutics and Pharmacy, Med Jurisprudence, Public Health, and Pathology Bacteriology. The subjects of the Fourth Exam tion are—Medicine, Clinical Medicine, Surg Clinical Surgery, Operative Surgery, Midwifery Gynæcology, Psychological Medicine, Diseases of Skin, of the Throat, Nose, and Ear, and of Child and Ophthalmology. It is required that at least on the five years of professional education shall be sp at the University of Durham College of Medic Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Maste Surgery* a candidate must not be less than 24 y of age. He must also have obtained the degree Bachelor of Medicine and Surgery of the Univer of Durham, and must have been engaged for at l two years subsequently to the date of admissio these degrees in research work, or in attendance the practice of a recognised hospital, or in the n or military services, or in medical or surgical prac The candidate for the M.D. degree may present essay or undergo a special examination in the subj of Medical Anatomy, Medical Pathology, and Principles and Practice of Medicine. The subject examination for the M.S. are:—Principles Practice of Surgery, Surgical Pathology, Surg Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The versity of Durham has instituted a special exam tion whereby the degree of Doctor of Medicine ma obtained without residence. Candidates must no under 40 years of age and must have been in ac practice for 15 years as registered medical p titioners. They must also produce certificate moral character from three registered member the medical profession. The fee is 50 guineas (inc ing the degree fee), of which 20 guineas is retain the candidate fails to satisfy the examiners.

Doctor of Surgery.—The University of Dur grants the Degree of Doctor of Surgery. Candid for this degree must be registered medical p titioners, and not less than 24 years of age. must devote three years, subsequently to obtai a registrable qualification, to the study of Sur and ancillary subjects. One at least of the t years must be spent in the University. The ca

must submit to the Professor of Surgery the se of study he proposes to follow, and this course t be approved by the Board of the Faculty of icine. One year shall be devoted mainly to work he departments of Anatomy, Physiology, Patho-, and Bacteriology, and the candidate must nit evidence of having so worked. Not less than nonths of another year must be spent as resident eon in a recognised teaching hospital, and the of the year in the study of surgery in a recog-d medical centre. Not less than six months of of the three years must be spent in surgical study ad.

ndidates for any of the above degrees, diplomas, cence must give at least 28 days' notice to the etary of Examinations, University of Durham ge of Medicine, Newcastle-upon-Tyne. In the of the M.D. (essay) examination candidates t send in their essays before April 1st.

cholarships and Prizes.—The following are rded :—University of Durham Entrance Scholar-, £25 a year for four years; Pears' Entrance larship, £40 a year for three years (awarded y third year; Heath Entrance Scholarship (from ier Grammar School), £60 (renewable); Province Durham Masonic (Entrance) Scholarship, £60 ewable); Heath Scholarship for Surgery, £200, lable every second year; Rutherford Morison ical Scholarship, £180, available every third year. ne following Scholarships are tenable for one year, ely :—Tulloch Scholarship for Elementary Biology Organic Chemistry, £20; Dickinson Scholarship Medicine, Surgery, Midwifery, and Pathology; t Medal and £20; Charlton Scholarship for Medi-, £25; Gibb Scholarship for Pathology, £28; e Armstrong Scholarship for Comparative Patho-, £25; Stephen Scott Scholarship for Surgery, ; Philipson Scholarships for highest marks in l M.B., B.S. Examinations, two of £48 each; der Memorial Scholarship for Clinical Medicine Clinical Surgery, interest on £325; Gibson Prize Midwifery and Diseases of Women and Children, ; Turnbull Prize and Silver Medal for Surface tomy; and Outterson Wood Prize for Psycho-al Medicine, £10; Sewell Memorial Prize and r Medal for Clinical Pathology.

or further information apply to the Dean of College.

OLLEGE OF MEDICINE, Newcastle-upon-Tyne.—pital practice is carried out at the Royal Victoria mary, a general hospital containing more than beds, and there are facilities for the study of the ous special subjects.

actical midwifery can be studied at the Princess y Maternity Hospital, which contains 90 beds, an annual indoor and outdoor attendance on cases.

ne bacteriological laboratory is adjacent to Arm-g College.

Students' Union has been erected and furnished cost of over £54,000, and is now in daily use. ial accommodation has been provided for women ents.

EWCASTLE-UPON-TYNE ROYAL VICTORIA INFIR-Y.—The Infirmary has 572 beds. Clinical ures are delivered by the Physicians and Surgeons dly and ward demonstrations are given daily. rial classes are held by specially appointed ical Tutors, Assistant Surgeons and Senior stant in the Gynæcological Department, and onstrations are given in the several out-patient rtments daily. Pathological demonstrations are n by the Pathologist daily or as opportunity rs, and in the new buildings nothing has been ed in perfecting scientific equipment. In addition nedical and surgical in-patient and out-patient rtments the following special departments are equipped for teaching students: Ophthalmic, at, Nose, and Ear, Skin, Gynæcological, and Elec-l. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory in which all clinical bacteriological investigations are carried out with a view to treatment by vaccines and serums. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1928 opens on Oct. 2nd and the summer session of 1929 on April 11th.

Applications for detailed information should be made to the Sub-Dean, Dr. Horsley Drummond, at the hospital.

Practical Midwifery is studied at the Princess Mary Maternity Hospital, a new building, excellently equipped, with 90 beds. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye.

Post-graduate Instruction.—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Venereal Diseases; Neurology; Diseases of Children; Electrotherapeutics and Radiology; special courses in Midwifery will be held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the early part of the Summer Vacation. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, and also at the Princess Mary Maternity Hospital, for specified periods.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Biology and Organic Chemistry. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof, and a recognised Pre-Medical Examination in Chemistry and Physics. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Part I., Elementary Biology and Organic Chemistry; Part II., Anatomy and Physiology. Second Examination.—General Pathology and Bacteriology, Materia Medica, and Pharmacy. Third Examinations (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, and Therapeutics. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the third examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months.

Vaccination instruction must be taken and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery. Distinctions may be awarded in the subjects (severally) of the First, Second, Third, and Final, and Honours in the Final Examination.

Degrees of Doctor of Medicine and Master of Surgery. At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver, for the Ch.M., or, at the discretion of the examiners, in a special branch of Medicine or Surgery respectively. A thesis of exceptional merit may exempt from any part of these examinations, in which Honours may be awarded.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year candidates may carry on research elsewhere, under approved conditions, and on completing the course present a thesis and submit themselves for oral and possibly written examination.

Scholarships and Prizes.—The following are awarded:—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland (available for year 1928–29); (*b*) two Ingleby Scholarships of £10 each awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*e*) Dental Scholarship of £37 10*s*., Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10*s*. each. In the First and Third Examinations the Scholarship is awarded respectively to the student taking the first place. In the Second Examination the Scholarship is awarded to the student obtaining the highest marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination and whose work is regarded as sufficiently distinguished of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal for Medicine) and the "Sampson Gamgee Memorial Medal" (Gold Medal for Surgery) are awarded annually to the best candidates passing Final M.B., Ch.B. Examination in June in Medicine and Surgery respectively, provided that not less than 60 per cent. of marks is obtained (paper, oral, and clinical). The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, res tively, in fourth and fifth years, open to all stude

Clinical Instruction.—The medical students of University receive their clinical instruction by att ing the amalgamated practice of the General Hosp Queen's Hospital, Maternity Hospital, Childr Hospital, Mental Hospital, and Fevers Hospital, u the direction of the University Clinical Bo Appointments are open to students varying £40 to £200 a year.

Post-graduate Instruction.—A "William Withe Lectureship" has been established. A course courses) of lectures is given annually for post-gradu on subjects chosen from year to year. In 1929 Lectures will be given by Dr. Charles Singer. Ingleby Lectures on some subject in connexion Diseases of Women and Children are given annu by specially appointed lecturers. Post-grad Courses of Clinical Demonstrations for General P titioners are arranged annually (April to July) at Birmingham General and Queen's Hospitals.

QUEEN'S HOSPITAL.—350 beds. There is a association of this Hospital with the Universit Birmingham, and the University clinical teachin conducted here, there being a wealth of excel material. Ward rounds and out-patient clinic cla are held daily, and there are regular tutorial cla throughout the session. Post-graduate cou arranged by the University are conducted every y There are special departments in Gynæcology, Dise of the Eye, of the Ear, Nose and Throat, Dentis Radiography, Pathology, Bacteriology, Biochemis Physiotherapy, and Electrocardiography. There also large Wards for Midwifery and Postnatal c a Nursery for instruction in Infant Welfare, extensive Midwifery District, and residential facil for students. There are 23 Resident Appointm (exclusive of Registrars) available each year recently qualified students.

BIRMINGHAM GENERAL HOSPITAL.—399 Special wards for Children, Gynæcological, Ear Throat, Venereal, Maternity, and Septic ca special beds for Eye and Skin cases. Laborat for Bacteriology and Morbid Histology. Sep rooms adjoin the medical and surgical wards clinical pathology. Five operating theatres (on out-patients), all designed and fitted on mo lines. In addition to clinical teaching given in wards and out-patient department by the hon staff, medical and surgical tutorial classes are for senior and junior students. Clinical instru in all the special departments, which include for Radium, Electrotherapy, Electrocardiogr investigation, and Venereal Diseases. Post-gra classes in every branch of medicine and sur The Jaffray Branch Hospital contains 61 beds.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Ch street, Birmingham.—115 beds. Students attendi a period of three months will be granted certif which will qualify for the University and Co Board examinations. Post-graduate courses available on various subjects, when a suff number of graduates are present. A limited nu of Non-Resident Clinical Assistants posts are ava to qualified practitioners, particulars of which c had on application to the General Superinten A fully equipped Ultra-Violet Ray Clinic and P logical Department have been opened this year.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Ba of Medicine and Bachelor of Surgery (M.B. and C Doctor of Medicine (M.D.), Doctor in Philo (Ph.D.), Master of Surgery (Ch.M.), Mast Hygiene (M.H.), and Master of Orthopædic S (M.Ch.Orth.).

Matriculation.—Important alterations in reg Matriculation requirements and to the Firs Second Years' courses of study will come operation in October, 1929. Particulars m obtained on application to the Dean.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of dicine and of Surgery must have attained age of 22 years on the day of graduation. At st two of the five years of medical study must e been passed in the University, and one year least must have been passed in the University sequently to the date of passing the First amination. The other three years may be passed any college or medical school recognised for s purpose by the University. Candidates must s three examinations entitled respectively: First Examination, the Second Examination, l the Final Examination. The subjects of First Examination are: (1) Chemistry; (2) ysics; (3) Biology (Zoology and Botany). The jects of the Second Examination are (*a*) (1) atomy; (2) Physiology (including Physiological emistry and Histology); and (*b*) (3) Elementary cteriology, (4) Clinical Chemistry, (5) General thology. Candidates may present themselves in or (*b*) separately. The subjects for the Final amination are: (*a*) (1) Special Pathology and rbid Anatomy; (2) Forensic Medicine and Toxi-ogy; (3) Public Health; (4) Pharmacology and neral Therapeutics; (*b*) (5) Obstetrics and Diseases Women; (6) Surgery, Systematic, Clinical, erative and Practical, including Ophthalmology; Medicine, Systematic and Clinical, including Thera-itics, Mental Diseases, and Diseases of Children. ndidates may present themselves in Parts (*a*) and separately, but candidates must have completed fifth year of medical study before taking t (*b*).

Degrees of Doctor of Medicine and Master of Surgery. candidate will be admitted to the degree of ctor of Medicine or Master of Surgery unless he previously received the Degrees of Bachelor of dicine and Bachelor of Surgery, and at least two rs have elapsed since he passed the examinations those degrees. Candidates for the degree of Doctor Medicine are required to present a thesis together h, if desired, published original work relative to lical science, and unless the thesis is of special it to submit to an examination in medicine, or a special written or oral examination on subjects nected with the thesis.

The University also awards a *Diploma in Medical Biology and Electrology*—Part I., Physics: Part II., Biology and Electrology. The parts may be taken one examination or separately.

Scholarships, Fellowships, and Prizes.—The follow-are awarded: (*a*) Robert Gee Entrance Scholar-p (Men), annually, of £42 10s., tenable for four rs; (*b*) Lyon Jones Scholarship, No. 1, of per annum, tenable for two years, Com-itive Examination among Junior Students in st M.B. Subjects; (*c*) Lyon Jones Scholar-p, No. 2, of £21, Competitive Examination on ults of Professional Examination in Anatomy, siology, Elementary Bacteriology, Clinical Chem-y, and General Pathology; (*d*) Derby Exhibition £15, Competitive Examination among Fourth-Fifth-year Students in Clinical Subjects, and (*e*) ical School Exhibition of £15 annually for Fourth-Fifth-year students; (*f*) University Scholarship £50 for one year, awarded on results of the Final rt A) Examination for the degrees; (*g*) Holt Fellow-ps, Physiology and Pathology, of £150 each, for one r; (*h*) Gee Fellowship, Anatomy, of £100, for year; (*i*) John Rankin Fellowships in Anatomy, , each of the value of £120, tenable for two years; Johnston Colonial Fellowship, Biochemistry, £100, for one year; (*k*) John W. Garrett Inter-ional Fellowship, Bacteriology, of £100, for one r; (*l*) Thelwall Thomas Fellowship, Surgical hology, of £150, for one year; (*m*) Ethel Boyce lowship in Gynæcological Pathology, of £100 for year; (*n*) Mary Birrell Davies Memorial Fund olarship, of the value of £60, tenable for four years, red for competition in alternate years; open only women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; (*p*) Lady Jones Research Fellowship in Orthopædic Surgery, £200; (*q*) Samuels Memorial Scholarships, three at £20; numerous prizes and medals.

The Medical School.—All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. There is also a separate building for Tropical Medicine. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation.

Clinical Studies.—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of six special hospitals—the Eye and Ear Infirmary, the Hospital for Women (with the Samaritan Hospital), Liverpool Maternity Hospital, the Royal Liverpool Children's Hospital, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1445 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine, a Diploma in Public Health, and a Diploma in Bacteriology are awarded by examination to registered medical practitioners.

***Degrees of Bachelor of Medicine and Bachelor of Surgery.*—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M.B. Examination.**

The First Examination: (1) Chemistry and Physics; (2) (*a*) Botany, (*b*) Zoology. Candidates must have attended during at least six months' courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part I, Inorganic and Elementary Organic Chemistry and Physics; Part 2, (*a*) Botany, (*b*) Zoology. The candidates sit for these parts separately. The Second Examination: (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. The Third Examination: (1) Pharmacology and Materia Medica; (2) Pathology. The Final Examination: (1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases

of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts: Part I., Forensic Medicine, Hygiene and Preventive Medicine; Part II., Medicine, Surgery, Obstetrics and Gynæcology (Systematic, Clinical, and Oral). Candidates for the Second Part must have completed the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Degrees of B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in Medicine who in their third year of study for the degree of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in Anatomy or Physiology, who are students in Medicine, are required to attend courses in advanced Anatomy and Physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science may proceed to the degree of M.Sc. by presentation of an approved thesis.

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at the Victoria University:—Scholarships: Dreschfeld Entrance (triennial), £20; John Russell Medical Entrance, £45; Sam Gamble Entrance for Women; Graduate Entrance (fees up to 160 guineas); two Dauntesey Medical Junior, £50 each; Dauntesey Medical Senior, £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology; Platt Physiological, £90; Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100; John Henry Agnew in Diseases of Children, £120. Fellowships: Leech Research, £70; Professor Tom Jones, Surgical, £105; Morrison Watson in Anatomy, £150; Delépine in Preventive Medicine (biennial), £300; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology, £15; Turner Medical, £20; Dumville Surgical, £15; Knight Prize in Psychological Medicine, £50; Graduate Prizes, £5 each. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities investigation are provided in Anatomy, Physiolo and Materia Medica. In the public health depa ment, which is lodged in a separate institute in Y Place, near the Royal Infirmary, suitable laborat accommodation is provided for the study of sanit chemistry, physics, and practical bacteriology in departments of chemistry and physics and in t of pathology.

Clinical Studies.—The clinical and practical depa ments of medical study are taught partly in Medical School and partly in the Royal Infirm and St. Mary's Hospitals for Women and Childr a fever hospital, mental hospitals, a convalesc home, and other special hospitals. Medical a Surgical Clinical Classes are conducted in the Infirma and separate instruction is afforded in the element Medical and Surgical Physical Diagnosis, in Obstet Medicine, Ophthalmic Surgery, and Pathologi Anatomy by the different members of the staff of Medical School and Infirmary.

Post-graduate Studies.—Post-graduate Courses Medicine and Surgery have been arranged for dur 1928–29 as follows, in addition to those usually h at the various hospitals: 1. Whole-time intens courses in (*a*) Medicine and Surgery, and (*b*) Obstet and Gynæcology. 2. Part-time courses in (*a*) Disea of the Eye, (*b*) Application of Radiology to Medic in Diagnosis and Treatment, (*c*) Diseases of the Sk (*d*) Clinical Pathology. 3. Clinical Assistantsh Syllabuses and other information may be had application to the Dean of the Medical Sch Manchester University.

MANCHESTER ROYAL INFIRMARY.—The M chester Royal Infirmary is built on the pavi system, near the University, and has accommo tion for 668 patients (including 54 beds at Central Branch). The medical side consists of f units, each unit having a testing-room for the scien investigation of morbid products and a class-ro The surgical beds are also arranged in five un each unit having its own operation theatre, v anæsthetising, recovery, sterilising, testing apparatus rooms, and its own class-room attacl All of these units are occupied. In the educati block is a large lecture theatre and a museum. In same building is housed the X ray department, wh has nine separate X ray outfits for different purpo and in which one large room is put aside speci for X ray demonstrations and teaching purpo A large massage school is also connected with department.

Associated with the Infirmary are: (1) the C valescent Hospital at Cheadle, containing 132 b (2) the Royal Lunatic Hospital at Cheadle, acc modating with its branches 430 patients; and (3) Central Branch in the City, which has now acc modation for 54 patients. The Associated Hosp thus contain 1230 beds and are under the s management. Women students are admitted on same terms as men.

Two Entrance Scholarships in Medicine of the v of £160 each are offered annually by the Counc the Manchester University and the Medical B of the Manchester Royal Infirmary for profici in Arts and Science subjects respectively. C scholarships and prizes are mentioned in the Co syllabus. Numerous annual appointments and ju appointments may be held by those who have atte the practice of the Infirmary.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pe bury, Gartside-street, Manchester, and Lyt St. Anne's.—The hospital contains 190 beds an in the Convalescent Home, Lytham St. Anne's. medical staff visit the hospital daily at 10 Clinical instruction is given by the medical at the Hospital and Dispensary. There is a Massage and Electrotherapeutic Department, an Artificial Sunlight Department. Four Cli Assistants are appointed for periods of months. In throwing open these appointm

qualified medical men and women, the Board ıctuated by the desire to aid those qualified lical men and women who wish to have oppor- ıties for the further study of disease in dren, or who wish to fit themselves for posts as lical Officers to Children's Hospitals, to Child fare Centres, or for School Medical Officer ointments. There is an Orthopædic Department. -patients' day is on Tuesday at Gartside-street, a ward at Pendlebury is devoted to cases needing ative treatment. Out-patients are seen daily at M. at the Out-patient Department, Gartside-street, ıchester. Secretary: Mr. W. M. Humphry.

ANCHESTER NORTHERN HOSPITAL FOR WOMEN CHILDREN, Park-place, Cheetham Hill-road, ıchester.—The hospital contains 73 beds. Out- ents are seen daily from 8.30 to 12 noon.

UNIVERSITY OF LEEDS.

our degrees in Medicine and Surgery are con- ed—viz.: Bachelor of Medicine and Bachelor of gery (M.B. and Ch.B.), Doctor of Medicine (M.D.), ter of Surgery (Ch.M.), also Degrees and Diplomas Dental Surgery and Diplomas in Public Health in Psychological Medicine. The courses and rees in the Faculty are open to men and women e.

egrees of Bachelor of Medicine and Bachelor of gery.—Candidates for these degrees are required resent certificates showing that they will have ined the age of 21 years on the day of graduation, have attended courses approved by the University nding over not less than five years, two of such s at least having been passed in the University, of which must be subsequent to the date of ing the First Examination. Candidates must also sfy the examiners in the several subjects of the owing examinations, entitled respectively: the riculation Examination, or such other examination nay have been recognised by the Joint Matricula- Board in its stead; the First Examination; the nd Examination; and the Final Examination. First Examination consists of: Part I., Physics Inorganic Chemistry; Part II., Zoology and any. Candidates will be allowed to pass the two s separately. The Second Examination consists Part I., Organic Chemistry; Part II., Materia lica and Practical Pharmacy; Part III., Anatomy, siology; Part IV., Pharmacology. Candidates be allowed to pass any parts separately, but Part nust be passed before Parts II., III., or IV. The al Examination consists of: Part I., Pathology and teriology; Part II., Medicine, Surgery, Obstetrics, ıæcology, and Clinical Pathology; Part III., ensic Medicine, Public Health, and Therapeutics. t I. may be taken at the end of the second clinical r, and Parts II. and III. may be taken at the end he third clinical year, but not before the completion he fifth year of medical study. If taken separ- y Part II. may be passed before Part III.

egree of Doctor of Medicine and Master of Surgery. andidates are not eligible for the degree of Doctor Medicine or Master of Surgery unless they have viously received the degrees of Bachelor of Medi- and Bachelor of Surgery of the University (or of toria prior to December, 1904) and at least two rs' Hospital Practice or four years' other pro- ional practice for the former, and one year has sed for the latter since they passed the examina- for those degrees. Candidates for the degree of tor of Medicine may present a dissertation and, he dissertation is considered to be of exceptional it, will not be required to pass an examination. first term commences on Oct. 1st. Prospectus be obtained from the Academic Sub-Dean.

ost-graduate work.—Practitioners wishing to attend rmary practice during short periods, or post- duate classes held by members of the clinical f, may do so on application to the Clinical Sub- n, from whom particulars may be obtained.

Clinical Studies.—The clinical studies are pursued mainly at the Leeds General Infirmary, which has accommodation for 630 in-patients, including 88 beds at branch hospitals in the country. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electrotherapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification. Further particulars concerning these, and the scholarships and prizes open to competition, may be obtained from the Dean of the Faculty of Medicine.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

***Degrees of Bachelor of Medicine and Bachelor of Surgery.*—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination. The subjects of the First Examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each. The Second Examination: The subjects are Anatomy and Physiology. Candidates must have completed the second year of professional study. The Third Examination: The subjects are Pathology, Pharmacology, Anatomy, and Physiology. Candidates must have completed the Lent Term of the fourth year of professional study. The Final Examination: The subjects of the examination are: Part I., Forensic Medicine and Public Health; Part II., Medicine (including Mental Diseases and Diseases of Children), Surgery, Obstetrics (including Gynæcology). Candidates for Part I. must have completed the Michaelmas Term of the fifth year of professional study; candidates for Part II. must have completed the fifth year of professional study.**

***Degree of Doctor of Medicine.*—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.**

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology and Bacteriology.

Scholarships and Prizes.—The following are awarded: Four Town Trustees scholarships, offered annually, each of the value of £50 per annum for three years. Medical: offered annually, covers cost of medical curriculum. Six Edgar Allen, offered annually, each of the value of £125 per annum for three years. Post-graduate: Frederick Clifford scholarship, value £50 per annum, tenable for two years. Mechanics' Institute scholarship, value £50 for one year, renewable for a second year. Town Trustees fellowship, value £75 for one year. Medals and Prizes: Kaye scholarship; Gold Medal in Clinical Medicine and Surgery; John Hall Gold Medal in Pathology; Holroyd Gold Medal in Anæsthetics; bronze medals. Particulars of all the above may be obtained from the Registrar.

The Medical School.—The Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain meals and refreshments at moderate prices. The University journal, *Floreamus*, edited by a committee of staff and students, is published each term. The University Halls, "Oakholme," Clarkehouse-road; "Tapton Cliffe," Fulwood-road, and "Endcliffe University Hall," Endcliffe Vale-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained from the tutor for women students. Stephenson Hall is a hall of residence for men students; particulars may be obtained from the Warden.

Clinical Studies.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes.

The SHEFFIELD ROYAL INFIRMARY (500 beds) provides all the opportunities of a large general hospital with special departments for Skin and Ear. The Sheffield Royal Hospital, 320 beds, has special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. The two institutions are amalgamated for the purposes of clinical practice, medical, surgical, and special. There are special departments for the treatment of Diseases of the Eye, with wards assigned to them, at both hospitals, and excellent junior appointments. The Jessop Hospital for Diseases of Women, with 142 beds, has also a Maternity department, with about 900 in-patients per annum and about 250 out-patient cases attended. The Children's Hospital has 85 beds. Special courses on Fevers are held at the City Fever Hospitals (690 beds) and on Mental Diseases at the South Yorkshire Mental Hospital (1860 beds). Every facility is afforded in the various laboratories for the prosecution of advanced studies and research.

Post-graduate Courses.—Post-graduate courses of clinical instruction are held annually in the various hospitals connected with the School.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass, at Matriculation standard, an examination called the School Certifi Examination, or to pass such examination as ma regarded as equivalent by the Senate. All cou degrees, and diplomas are open to men and wo alike.

Degrees of Bachelor of Medicine and Bach of Surgery.—Candidates shall be not less t 21 years of age and shall have pursued the cou prescribed by University Regulations during less than five years after passing the first ex nation in Chemistry and Physics, of which three s have been passed in the University, and two of t three subsequent to passing the second examinat All candidates for the degrees of M.B., Ch.B., required to satisfy the examiners in the sev subjects of three examinations. The First Exam tion: The subjects of examination are: Chemi (Inorganic), Physics, and Biology, the courses sued being those for the time being approved the intermediate part of the B.Sc. curriculum. part of the curriculum shall extend over one y (Candidates who have passed the Higher Sc Certificate approved by the Board of Educatio these subjects will not be required to sit for first examination and will be regarded as ha completed one year of study.) The Second Exam tion: The subjects of examination are: Org Chemistry and Elementary Anatomy (Part I.) Advanced Anatomy and Physiology (Part The Final Examination: The subjects of exam tion are: Materia Medica and Pharmacy, Pha cology and Therapeutics, General Pathology, Mc Anatomy, and Bacteriology (Part I.); Special Pa logy, Forensic Medicine, Toxicology, and P Health, Obstetrics (including Diseases of Wom Surgery (Systematic, Clinical, Practical, and O tive), Medicine (Systematic, Clinical, and Prac including Mental Diseases) (Part II.). The sub included in Part II. may be taken in two grou viz., Group I., Surgery and Obstetrics; Group Medicine, Public Health, Special Pathology, For Medicine, and Toxicology. Candidates may Parts I. and II. together, or separately, and the groups of Part II. may be taken together or separa Forensic Medicine and Toxicology may be taken Part I., or with Group II. of Part II.

Degree of Doctor of Medicine.—Candidates sha Bachelors of the University of not less than two y standing as such and may elect either (1) to pa examination in General Medicine, or (2) to pas examination in State Medicine, or (3) to prese Dissertation. The candidate who elects to the examination in State Medicine must a diploma in Public Health of some Unive or College, and the candidate who elects to pr a Dissertation may be examined in the su thereof.

Degree of Master of Surgery.—Candidates sha Bachelors of not less than two years as such, d which period they shall have attended the Su Practice of an institution approved for the pu They shall pass an examination in Surgical Anat Pathology, and Bacteriology, and Operative, Cli and General Surgery, and present to the Univer Dissertation on some subject of Surgery. The d may be taken also in General Surgery, and a S Subject—e.g., Oto-Rhino-Laryngology, Ophth logy, and Gynæcology.

Clinical Studies.—The allied hospitals (BR ROYAL INFIRMARY and BRISTOL GENERAL HOSP have between them about 600 beds and exte out-patient departments, special clinics for Di of Women and Children and those of the Eye, T and Ear, in addition to large and well-equ departments for Dental work and large ou Maternity Departments.

At each of these institutions there are well-arr pathological museums, post-mortem rooms, laboratories for Morbid Anatomy. There are laboratories for work in Clinical Pathology, Bac logy, and Cytology, in which special instruct

n in these subjects. Departments are provided well equipped for X ray work, both for diagnosis treatment, the various forms of Electrical tment, including High-frequency Currents, tric Baths, Finsen Light treatment, and Massage.

he students of the school also attend the practice he Royal Hospital for Sick Children and Women, aining 140 beds, and that of the Bristol Eye pital, with 40 beds. The total number of beds ilable for clinical instruction is therefore about

here are numerous salaried junior appointments residents who are graduates.

cholarships and Prizes.—The following are awarded: Ashworth Hallett Scholarship, value £45, open women only; two Martin Memorial Pathocal Scholarships of £10 each; the Tibbits norial Prize, value 9 guineas, for proficiency in tical surgery; the Committee's Gold and Silver lals for fifth-year students for general proficiency; Augustin Prichard Prize, value about 6 guineas, for iciency in anatomy; the Henry Clark Prize, ie 11 guineas, for proficiency in gynæcology; the sby Leonard Prize, value 7 guineas, for proficiency urgery; the Suple Surgical Prize, a gold medal 7 guineas; the Suple Medical Prize, a gold medal 7 guineas; the Henry Marshall Prize, value £12, dressers; the H. M. Clarke Scholarship, value , for proficiency in surgery; the Sanders Scholarp, value £22 10*s.*, for general proficiency; the rett-Roué Scholarship for proficiency in diseases he eye, ear, nose, and throat, value £14; Lady erfield Scholarship, value about 25 guineas; llis Siepman Prize, for proficiency in Diseases of dren, value £25.

ristol City Senior Scholarships and those offered the counties of Gloucestershire, Somerset, Wilts, Devon, are tenable in the University. Some of Fellowships awarded by the Colston Research iety for research in the University are allotted to Faculty of Medicine.

ost-graduate Study.—Qualified medical practiers may be appointed as clinical assistants for a iod of one or more months. They may act as stants, if times permit, in more than one departnt and in any of the hospitals during their period study. They will be entitled to the use of the ical laboratories and medical library, and have the t to attend in all departments, including operas, post-graduate and ordinary clinical demonstras, and post-mortem examinations. Demonstration rses with weekly lectures are held during May, e, and July.

ll inquiries and applications for admission should addressed to the Director of Post-graduate dies (Clinical Section), Pathological Department, versity of Bristol, who can be seen on any day appointment.

urther information as to scholarships, curricula, fees can be obtained from the Dean of the Faculty Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

his University has, inter alia, the privilege of nting Degrees in Medicine, and Diplomas in Public alth and Tuberculous Diseases. Preliminary rses of study for the Degrees in Medicine may be sued at any of the constituent Colleges of the iversity—viz., at Aberystwyth, Bangor, Cardiff, or ansea. The Welsh National School of Medicine situated in Cardiff and is an integral part of University College of South Wales and nmouthshire there.

articulars can be obtained on application to Dean of the Faculty of Medicine, or to the retary, Welsh National School of Medicine, wport-road, Cardiff. All classes are open to both n and women students.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England, and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Students are required to pass a Preliminary Examination in General Education recognised by the Board, and a *Pre-Medical Examination* in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognised by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any University recognised by the Board; a Pre-Medical Examination conducted by any of the Qualifying Bodies whose Degrees or Diplomas are registrable on the Medical Register; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education. The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months. The fee for the examination is £3 3*s.*, for re-examination in Chemistry £2 2*s.*, and for re-examination in Physics £1 1*s.*

There are two Professional examinations called the *First* and *Final Examinations*. The courses of study for these examinations may be commenced before the Pre-Medical examination in Chemistry and Physics or some equivalent examination has been passed, provided that three terms of study are completed after the examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology. (*b*) Physiology, including Biochemistry. Section II. Pharmacology, Practical Pharmacy, and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Biochemistry and Biophysics during five terms, courses of instruction in Pharmacology, Practical Pharmacy, and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together

until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s.*, for re-examination after rejection in Section I. £6 6*s.*, for re-examination after rejection in either part of Section I. £3 3*s.*, for re-examination after rejection in Section II. £3 3*s.* A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology), and Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from Section I. The fee for admission to Section I. is £4 4*s.*; for admission to Section II., Part I., £10 10*s.*; Part II., £10 10*s.*; Part III., £6 6*s.*; and the re-examination fees are respectively £3 3*s.*, £6 6*s.*, £6 6*s.*, and £4 4*s.*

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First Examination of the Examining Board, may enter for a part of the Final Examination at the expiration of three years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First Examination may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, and in Laryngology and Otology. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, London, W.C. 1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years. The alteration in the by-law of the College is designed to enable men who have j finished house appointments to sit for an examinat for which their recent clinical experience has exac fitted them. The candidate must either have pas the examinations for the licence of the College, else be a registered medical practitioner who l obtained the degree of Doctor or Bachelor of Medic at a University recognised by the Censors Boa The examination is directed partly to patholo and partly to the practice of medicine. Credit also given to candidates who show a knowledge Latin, Greek, French, or German. Further inform tion may be obtained from the Registrar at College. The fee for admission as a Member of College is 40 guineas, except when the candidate membership is a licentiate of the College, in wh case the fee already paid for the licence deducted from the 40 guineas. The fee for examination is 8 guineas, which is reckoned part of the fee for admission in the case success.

Fellowship.—The *Fellows* are selected annua from the ranks of the *Members* by the Comitia of College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:

THE FELLOWSHIP.

The Royal College of Surgeons of England conf its diploma of Fellow upon a few distinguished pers in an honorary capacity. Two Members of l standing may also be elected to the Fellows annually. But the bulk of the Fellows obtain diploma as the result of examination.

Fellowship.—The examination for the Fellowshi divided into two parts—viz., the First Examinat and the Second Examination. The subjects of First Examination are Anatomy and Physiology, a those of the Second Examination are Surgery, includ Surgical Anatomy and Pathology. The examinati are partly written and partly vivâ voce, and incl the examination of patients and the performance operations on the dead body. The First Exami tion will in future years be held in June a December and the Second Examination in May a November.

The fees for examination are: First Examinati first admission 8 guineas, and for each readmiss 5 guineas. Second Examination, each admiss 12 guineas. The fee payable on admission to Fellowship by Members is 10 guineas and by n Members 30 guineas, in addition to examination f

A Member of the College is admissible to the F Examination at any time after receiving his Diplo of Membership. A candidate who is not a Membe admissible after passing the First Professional Exa nations of the English Conjoint Board in Anato and Physiology, or the equivalent examination in University, on the production of certificates attendance upon prescribed courses.

A Member of the College is admissible to the Sec Examination at any time after having passed First Examination, on producing evidence of hav been engaged not less than six years in the st (or study and practice) of the profession.

A candidate who is not a Member of the Coll must possess the registrable surgical and med degrees of universities recognised by the Council must have been engaged in the study (or study practice) of the profession for not less than four ye subsequent to the date of obtaining the recogni qualification, one year of which shall have been sp in attendance on the Surgical Practice of a recogni hospital. The diploma of Fellow is not confer upon successful candidates until they have attai the age of 25 years.

The Regulations may be obtained on applicatio the Secretary, Examining Board in England, Ex ination Hall, Queen-square, London, W.C. 1.

OCIETY OF APOTHECARIES OF LONDON.

he Pre-Medical and Primary examination is held rterly. Part I. includes Chemistry, Chemical sics; Practical Chemistry; Materia Medica and rmacy. Part II. includes Anatomy, Physiology, Histology. This examination cannot be passed re the completion of twelve months' Practical tomy with Demonstrations, and these subjects not be taken separately except in the event of the didate having previously passed in one.

he Final examination is held monthly except in tember. Part I. Clinical Surgery: Principles and ctice of Surgery, Surgical Pathology, and Surgical tomy, Operative Manipulation, Instruments, and liances. Part II. Clinical Medicine: Medicine, rmacology, Pathology, and Morbid Histology; ensic Medicine, Hygiene, Theory and Practice of cination; and Mental Diseases. Part III. includes wifery, Gynæcology, and Diseases of New-born dren and the Use of Obstetric Instruments.

he course of study for the *Final examination* ides attendance on the Surgical and Medical ctice, with Post-mortem Examinations, at a ital connected with a medical school for a period hree winter and three summer sessions, including urse of Practical Midwifery, with attendance on 20 wifery cases. The course of medical study must nd over five years, and the office of dresser or cal clerk must be held at a hospital or other insti- on recognised by the Society. Three academic s (33 months) must elapse after a candidate has ed the examination in Anatomy and Physiology re he can complete the Final examination.

vidence shall also be given of practical instruction nfectious Diseases and in Mental Diseases (at a tic asylum or in the wards of an institution con- ing a special ward set apart for the treatment of tal diseases), and in any two of the following ects: Ophthalmic Surgery, Laryngology with nology and Otology, Dermatology, and Diseases hildren. Candidates intending to present them- es for examination are required to give 14 days' ce. The fee for the Licence is 20 guineas. Female lidates are admitted to examinations.

laster of Midwifery.—This diploma has now been tuted and the first examinational session will be Monday, Oct. 15th, 1928. Candidates will be itted to the examination who have been regis- d practitioners for at least one year, and who have a resident appointment in an institution gnised by the Society for six months or more, and for three months have attended an antenatal c and an infant welfare centre, also recognised he Society. Until 1932 practitioners of ten years' ding may enter for the examination without further ality than the production of satisfactory evidence they have made a special study of the subjects. examination will be conducted by written papers by clinical and oral tests.

he entrance fee for the examination is £5 5*s.* and a ner fee, which at present is fixed at £5 5*s.*, will paid before their admission to the Mastery, by e who have satisfied the examiners. Candidates for first examination must send in their certificates re Oct. 1st to the Secretary of the Society, Mr. k Haydon, who will supply any other information.

he examination offices are open from 10 A.M. to M.; on Saturdays from 10 A.M. to 1 P.M. All rs should be addressed to the Secretary, Court xaminers, Society of Apothecaries of London, kfriars, E.C. 4.

PHARMACEUTICAL SOCIETY.

HOOL OF THE PHARMACEUTICAL SOCIETY OF AT BRITAIN (recognised by the UNIVERSITY OF DON).—The Pharmaceutical Society conducts inations for registration as (*a*) Chemist and gist and (*b*) Pharmaceutical Chemist. For tration as Chemist and Druggist the candidate pass (i) the Preliminary Scientific Examination jects Chemistry, Physics, and Botany); and (ii) the Chemist and Druggist Qualifying Examination (subjects Pharmacognosy, Pharmacy, Pharmaceutical Chemistry, and Forensic Pharmacy). Fee for each examination, 6 guineas; for each subsequent examination after failure, 4 and 6 guineas respectively. The Pharmaceutical Chemist Qualifying Examination (for registration as Pharmaceutical Chemist) includes Botany, Chemistry, Pharmacognosy, Pharmacy, and Forensic Pharmacy. Candidates must have passed the Preliminary Scientific Examination. Fee, 12 guineas; for each subsequent examination after failure, 6 guineas. Courses of Instruction are given for the Chemist and Druggist Qualifying Examination, and (two years' course) for the Pharmaceutical Chemist Qualifying Examination in conjunction with University College.

An Intercollegiate two years' course for the Final Examination for the degree of B.Pharm. of the University of London is also given in conjunction with University College. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates in Science may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories. Application for admission to the school, or for further information, may be made to the Dean, Prof. Greenish, 17, Bloomsbury-square, London, W.C. 1.

The *London College of Pharmacy for Ladies*, 7, Westbourne Park-road, W.2, which is under direct medical supervision, offers a nine months' course of instruction to women in preparation for the Apothecaries' Hall Diploma in dispensing.

METROPOLITAN CENTRES AFFORDING POST-GRADUATE FACILITIES.

Certain organisations and institutions provide for the needs of the medical student in his cirriculum and for the post-graduate student requiring special forms of instruction and opportunities for clinical observation. Many of the institutions are recognised by the English Conjoint Examining Board as a place of study for the fifth year of the curriculum.

Special Diplomas in public health, tropical, psychological, and ophthalmic medicine, medical radiology and electrology, laryngology, otology, and tuberculosis are now granted in proof of intensive work along the different lines indicated. Of these, the Diploma in Public Health, being regulated by the General Medical Council, is registrable. Appointments to and promotion in the various Services are largely dependent on the possession of a particular diploma, and each syllabus of the special courses available at the institutions which follow, either with or without association with the Fellowship of Medicine, is planned to afford the necessary instruction.

The Special Diplomas are dealt with fully on p. 420, where the connexion between the Bethlem Royal Hospital and the Maudsley Hospital and the Diploma in Psychological Medicine is referred to. Similarly the Hospitals of the Metropolitan Asylums Board provide post-graduate as well as under-graduate facilities, while the hospitals of the Seamen's Hospital Society both supply the instruction necessary for the Diploma in Tropical Medicine and Hygiene, and coöperate in the activities of the Fellowship of Medicine and Post-Graduate Medical Association.

HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.—These hospitals, of which there are 18 in the metropolis and the near vicinity, will shortly come under the administrative powers of the London County Council. The Board hold classes of instruction in fevers at all the infectious hospitals at which ordinary medical students attend, but the only hospital to which

a class of instruction for the diploma in public health is attached is the North-Eastern Hospital. This course of lectures and demonstrations (three months) on clinical practice and in hospital administration is given at the North-Eastern Hospital, St. Ann's-road, Tottenham, N. 15, by the medical superintendent, on Mondays and Wednesdays at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning Monday, Oct. 1st, 1928. This course complies with the requirements of the revised D.P.H. regulations of the General Medical Council. Application for further information should be made to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, London, E.C. 4.

SEAMEN'S HOSPITAL SOCIETY.—The Society possesses seven establishments: the Dreadnought Hospital at Greenwich, 250 beds; the Albert Dock Hospital, E. 16, 53 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, W.C. 1, 58 beds; Tilbury Hospital, Tilbury Docks, Essex, 80 beds; Queen Alexandra Memorial Hospital, Marseilles, 60 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds; and the Angas Home, Cudham, 36 beds. Total, 617 beds. It has also a Dispensary in the East India Dock-road from which patients are transferred to the hospitals. In conjunction with the Fellowship of Medicine arrangements have been made for a course of operative surgery at the Dreadnought Hospital.

The London School of Hygiene and Tropical Medicine is located in the same building as the Society's Hospital for Tropical Diseases at 23, Endsleigh Gardens, Gordon-street, W.C., and the clinical teaching of the School is given in the Hospital (see p. 420).

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

Certain hospitals or groups of hospitals are working in conjunction with this Association, which has its office in the House of the Royal Society of Medicine, 1, Wimpole-street, W.1. It provides intensive courses in general and special branches of medicine and surgery, which are arranged at short intervals, and also courses in special subjects the nature of which are indicated by the groups of hospitals coöperating in its teaching work. Demonstrations in clinical medicine, in surgery, and in ophthalmology are arranged also from October to July, and are open to all members of the medical profession without fee. Membership of the Fellowship is open to all qualified medical practitioners, the membership fee being 10*s.* per annum, which includes the subscription to the monthly *Post-Graduate Medical Journal*. Full information regarding the courses of study can be obtained from the Secretary.

GENERAL PRACTICE.

ROYAL NORTHERN GROUP OF HOSPITALS.—The Royal Northern Hospital, Holloway, London, N. 7, is the main institution of the Royal Northern Group of Hospitals, which includes the Royal Chest Hospital, City-road, E.C., Hospital of Recovery, Southgate, and the Reckitt Convalescent Home, Clacton-on-Sea. The total number of beds in the group is 400. Besides the honorary staff there are six anæsthetists, three pathologists, resident medical officer, resident house physician, three resident house surgeons, two resident casualty officers, and one resident obstetric surgeon. The large rectangular and circular wards, each of which contains 25 beds, the children's ward for children under 5 years of age, the observation wards in the new Casualty Department, the two operation theatres, and out-patient department are designed with a view of offering the greatest facilities for clinical work. The Special Departments include the following: Fracture, genito-urinary and neurological, physico-therapeutic, pathological (under a director of clinical pathology), tuberculosis, venereal diseases, and X ray (recently remodelled). Patients are removed to the Hospital of Recovery by ambulance a few days after operation. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological c are appointed in the general and special departn and may receive certificates at the end of their t of office. NEUROLOGY.

HE NATIONAL HOSPITAL, QUEEN-SQUARE, W.C.—hospital, with the Convalescent Home at East hley and branch at Clapham Park, contains 265 and cots The out-patient physicians attend every day, Tuesday, Thursday, and Friday at 2 P.M., the physicians daily. Clinical clerks are inted under physicians and clinical assistants to patient physicians. Post-graduate Courses of ures and Demonstrations are held three times y year, usually commencing in January, May, and ber, and lasting eight weeks. Special Courses in ological Ophthalmology, Neuropathology, and Anatomy and Physiology of the Nervous System given. The Pathological Laboratory is available pecial work under the Pathologist.

EST END HOSPITAL FOR NERVOUS DISEASES.—institution is recognised by the University of lon as a school of instruction in Neurology for M.D. degree, Branch III., and for the D.P.M. Out-patient Department is in Welbeck-street, W.; In-patient Department is at Gloucester-gate, nt's Park, and contains 80 beds. Completely oped with pathological and other special depart-s, the hospital offers every facility for instruction eurological subjects. In conjunction with the lem Royal Hospital, it offers courses of instruction he D.P.M. Additional series of clinical demon-ions, apart from the general practice of the ital, are held regularly each session, and the ital coöperates with the Fellowship of Medicine e programmes of special post-graduate teaching nised by the Association. Appointments as Clinical Assistants in the Out-patient Depart-are open to registered medical practitioners. Savill Memorial Prize (value £15) and Medal are ed biennially for competition among post-uate students who have attended the practice e hospital or any special course. Full particulars be obtained from Dr. C. C. Worster-Drought, ., or J. P. Wetenhall, Secretary, 73, Welbeck-t, W.

OSPITAL FOR EPILEPSY AND PARALYSIS, &C., a Vale, W. (85 beds).—Both in-patient and out-nt departments of this hospital are open free to nts as well as to medical graduates. The patient department is open every week-day ot Saturday at 2 P.M.

HEART AND LUNGS.

OSPITAL FOR CONSUMPTION AND DISEASES OF THE RT, Brompton.—The hospital contains 333 beds. Sanatorium at Frimley contains 100 beds and eds for paying patients. Six house physicians e in the hospital for a term of six months; their s include attendance in the out-patient depart-. An additional month may be spent at the torium. Pupils are admitted to the practice of hospital. Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical assistants are appointed to the physicians in the out-patient department and clinical clerks to the physicians in the wards. The medical practice of the hospital is recognised by the English Conjoint Board and also by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital is open to post-graduates and students. During the month previous to each conjoint examination the teaching will be as far as possible for students about to enter for the final examination. The hospital practice is open to post-graduate students.

MOUNT VERNON HOSPITAL (INCORPORATED) FOR TUBERCULOSIS AND DISEASES OF THE LUNGS AND HEART, Northwood; CENTRAL OUT-PATIENT DEPARTMENT, Fitzroy-square, W.—The hospital contains 150 beds, Medical and Surgical; 50 beds reserved for children requiring surgical aid. Clinical Demonstrations are given by the visiting Medical Staff at the hospital at Northwood. New departments for artificial light treatment have been opened both in the hospital and the out-patient departments. Clinical assistants are appointed to physicians in the wards and in the out-patient department.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. 2.—Tuberculosis Dispensary (Boroughs of Bethnal Green and part Hackney). Special Departments: Surgical, Laryngological, Radiological, Pathological, Electrocardiographic. Assistants are appointed to the Clinics, and a limited number of research workers to the Pathological Department. The in-patient staff visit generally in the afternoon; out-patients at 2 P.M. The post-graduate students are admitted on payment of fees which entitle them to attendance at clinics, post-mortem demonstrations, and operations. Special demonstration and lecture courses are provided, and a club room. Graduates desiring Assistantships in any department should apply to the head of the Special Department.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, London, W. (founded 1857).—The practice of the hospital, both in the wards and out-patient department, is open daily to post-graduates and others. Systematic courses of instruction, with lectures and clinical demonstrations, are arranged during the winter and summer sessions; in addition an intensive course, of a fortnight's duration, takes place in January, July, and October of each year. The hospital is fully equipped with all the modern instruments for the investigation of the diseases of the Cardiovascular system, and facilities exist for those requiring practical instruction in Electrocardiography, X Rays, and other graphic methods. Clinical Assistants in the Out-patient Department are appointed from time to time.

DISEASES OF WOMEN AND CHILDREN.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. 1. (contains 252 beds).—The practice is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to eight medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Clinical Clerks are appointed once a month. In the pathological department facilities are afforded to post-graduates for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology, and in Medical Biochemistry in the Pathological and Biochemical Laboratories. Courses of eight to ten Lecture-Demonstrations are given at weekly intervals twice a year in both subjects

(Clinical Pathology and Bacteriology, and Biochemistry.) Time spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, as well as by the English Conjoint Board as part of the final curriculum. These appointments are open to students of all recognised medical schools. In addition, special lectures in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL (formerly QUEEN CHARLOTTE'S LYING-IN HOSPITAL) AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—This hospital receives over 2000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. They also receive valuable instruction in the Antenatal Department, where over 4000 patients attend yearly. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and maternity nurses are received and specially trained. A Residential College provides accommodation for students and qualified practitioners (both men and women), and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Bridge-road, S.E.—This hospital, founded at the date indicated by its title, has recently undergone considerable extensions, and has now 130 beds, while the latest buildings include a nurses' home and a new operation theatre. It has a full staff of surgeons, physicians, and gynæcologists, and also special departments. A new orthopædic department is in use, and a new nursing home is in occupation. The physiotherapeutic and electrical department has this year been extended and re-equipped. Particulars of post-graduate courses, which are held from time to time, can be obtained from the Secretary or from the Fellowship of Medicine.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—138 beds and a large out-patient department; the home at Broadstairs has 50 beds. Private wards in the Nurses' Home, named after H.R.H. Princess Mary (Viscountess Lascelles), at 29, Tite-street, adjacent to the hospital. Patients must be under the care of a consultant of one of the hospitals of London, and the question of payment for his fees is arranged between him and the child's parents. Application for admission should be made to the Secretary.

QUEEN'S HOSPITAL FOR CHILDREN (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E.2.—For the sick children of the poor under 14 years of age. 134 beds in London and 36 at the seaside branch, "Little Folks" Home, Bexhill.—Special departments in Ear, Nose, Throat, Skin and Eye, and Dentistry. A radiologist attends four times weekly. There are massage and light departments, and a special whooping-cough physician. The practice of the hospital is open to students by arrangement with the medical staff, and post-graduate instruction in children's diseases, lectures and demonstrations are given at times notified by the Fellowship of Medicine.

PADDINGTON GREEN CHILDREN'S HOSPITAL (46 beds).—This is a small hospital with a large out-patient department and a full staff, with eye, ear, skin, and dental departments. The facilities which it offers for observation of clinical practice are used by the Fellowship of Medicine.

HOSPITAL FOR WOMEN, Soho-square, W. (80 be —The teaching is available for post-graduates o in limited numbers. Operations take place dail 2 o'clock except on Saturdays. The X ray dep ment is supplied with the latest installation for diagnosis and treatment, and experience also be gained in the treatment of malignant dis by means of radium. Incorporated is the Lon School of Gynæcology, comprising attendance out-patient department, operating theatre, clin lectures, and X ray treatment.

SAMARITAN FREE HOSPITAL FOR WOMEN, Mar bone-road, N.W. (70 beds).—Qualified practitio are admitted as clinical assistants to both in- and out-patient departments. Full particu in regard to fees may be obtained on appl tion to the Secretary to the Medical Committe the hospital.

EAST LONDON HOSPITAL FOR CHILDREN DISPENSARY FOR WOMEN, Glamis-road, Shadwell —136 cots. Clinical instruction is given by physicians and surgeons to the hospital to stud in the fifth year of the curriculum. Two clin clerkships for qualified or unqualified students open every three months subject to reappointme desired. Clinical assistants (qualified men only) from time to time appointed in the out-pat department. Any additional information may obtained on applying to the Secretary.

The class meets at 5 P.M. on Tuesdays Fridays, and the instruction, which is practical, pplemented by lantern demonstrations. Full culars from the Secretary, 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: *M.B.* and *Ch.B.* (always conjointly), *M.D.* and *Ch.M.*; *B.Sc.* in Public Health; *D.Sc.* in Public Health; *B.Sc.* in Pharmacy; and *Ph.D.* in the Faculty of Medicine. A Diploma in Public Health (*D.P.H.*) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must attend a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine with nine months more of general hospital practice; the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects: Ophthalmology, Diseases of the Ear, Diseases of the Throat and Nose, Venereal Diseases, Tuberculosis, Fevers, Vaccination. The final year consists of three intensive terms of study one devoted to Midwifery and Diseases of Women, one to Surgery, and one to Medicine.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases Peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are granted to candidates, not under 24 years of age, who have previously obtained the double bachelorship on completing examinations, in Clinical Medicine for M.D. and in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M. The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or

equivalent diploma) from an approved University or College and must prosecute a course of special study or research for two or three years and given evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject matter of the thesis.

Post-graduate Medical Teaching is available under the auspices of Glasgow Post-Graduate Medical Association, which is representative of practically all the Teaching Institutions in Glasgow. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. There is a General Medical and Surgical Course during the last two weeks of August and the first two weeks of September. This is a whole-time course and includes most of the subjects of interest to the general practitioner. The forenoons are occupied with General Medicine and Surgical Diagnosis and Minor Surgery in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in some of the special hospitals or in the special departments of the general hospitals—two subjects each afternoon. On the four Saturday forenoons Tuberculosis and Infectious Fevers are demonstrated at Ruchill Fever Hospital. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from the Secretary of the Association, 9, Woodside-terrace, Glasgow.

The great majority of the students take their hospital course at the Western, Royal, and Victoria Infirmaries, and at the district hospitals of Glasgow Parish Council, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, Insanity, and Electro-diagnosis and Therapeutics.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the Infirmary. New Lectureships in Materia Medica and Pathological Biochemistry were established recently, and this year a lectureship in Bacteriology has been founded. St. Mungo's College which embraces and continues the original Royal Infirmary Medical School, is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, over 800 beds. There are special wards for diseases of women, of the throat, nose, and ear, skin, eye, burns, septic cases, and biochemical investigation. The wards are open to Women Students. In addition to the large medical and surgical departments, there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and ten house surgeons, who board in the hospital free of charge, are appointed every six months; also five non-resident house physicians, eight non-resident house surgeons, and one non-resident dental house surgeon. Clerks and dresses are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received, these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion and Massage Department, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Cla are held during August and September in Cli Medicine, Clinical Surgery, Clinical Gynæcol Diseases of the Skin, Biochemistry, Diseases of Throat, Nose and Ear, and in Diseases of the Tutorial Classes for senior students are also in August and September.

For information regarding fees and other particu application should be made to the Superintendent

GLASGOW WESTERN INFIRMARY.—This hospita 600 beds adjoins the University. Special wards set apart for Diseases of Women, Throat, Nose, Ear, and for Affections of the Skin. In the out-pat department there are special clinics for Disease Women and for Diseases of the Throat, Ear, Te Skin, Venereal Disease, and Electrotherapeutics. Clinical Courses are given by the physicians and geons, each of whom conducts a separate class, students require to enter their names at the begin of the session for the class which they propos attend. Special instruction is given to junior stud by tutors or assistants, and clinical clerks and dres are selected from the members of the class. All courses of clinical instruction are recognised by University of Glasgow and the other boards the kingdom. In the Pathological and Bacteriolo Departments the courses are both systematic practical, and extend through the winter and fol ing summer; these are likewise recognised by University for graduation. In addition Post-grad Courses are held. Eighteen resident assistants appointed annually, without salary, from those have completed their course. In the Clinical Lab tory students receive laboratory instruction from lecturer on clinical methods. A School of Mass Medical Electricity, and Swedish Remedial Exer has been established to qualify for the Certifica the Chartered Society of Massage and Me Gymnastics. Secretary: J. Matheson Johnston, 87, Union-street.

VICTORIA INFIRMARY, 67, Carlton-place, Glasgo This institution, which has 380 beds, is the thir the extensive general hospitals in Glasgow to a opportunity for clinical instruction to students. addition to a full general staff there is a cli research laboratory with pathologists and bact logists attached, radiological and dental instruc and a full assortment of specialists. The Bellahou Dispensary, also with a clinical staff, is conduct connexion with the Victoria Infirmary. For fu particulars of the clinical practice application sh be made to the Secretary and Treasurer, Mr. Joh Robson.

THE ANDERSON COLLEGE OF MEDICINE, Dumba road, Glasgow, W.1.—Courses are given which qu for all the licensing boards and for the Universiti Oxford, Cambridge, London, Durham, Edinbu and Glasgow (the latter two under certain conditi Extensive accommodation is provided for Prac Anatomy, Practical Chemistry, Practical Bo Practical Zoology, Practical Physiology, Prac Pharmacy, Operative Surgery, and Public He Ample provision has also been made for the co of students. Women students are admitted o same terms as men, and the Carnegie Trust ex its benefactions to students of the College. particulars may be obtained from the Carnegie Offices, Merchants' Hall, Edinburgh.)

Candidates for the L.D.S. can obtain the medical curriculum in Anatomy, Chemistry, Ph logy, Surgery, Practice of Medicine, and Ma Medica. The courses special to Dentistry are ducted at the Dental Hospital, Glasgow.

Communications relating to the College t addressed to the Secretary of the Medical Fac Communications relating to the Preliminary Exa tion in General Education to be addressed t Educational Institute Office, 47, Moray-place, burgh; and relating to the Triple Qualificatio to the Dental Qualification to be addressed to Faculty Hall, 242, St. Vincent-street, Glasgow.

UEEN MARGARET COLLEGE (Women's Department he University).—This is an integral part of the versity of Glasgow. The classes are taught by essors of the University and other lecturers ointed by the University Court, and it is governed he University Court and Senate. The curricula, lations, and fees are the same as those of the male lents, and the University degrees are open to nen on the same conditions as to men. The ol of medicine is a special feature of the College, gives full preparation for the medical degrees of University. The women students attend classes he various University Buildings at Gilmorehill Queen Margaret College, the Royal Infirmary, Western Infirmary, and the Victoria Infirmary. lities for clinical work are given in the Royal, tern and Victoria Infirmaries, in the Maternity, al Sick Children's, and other hospitals. The nur Scholarship is open every third year to students rst year; other Bursaries are open in Arts and icine, and women are admitted to certain versity bursaries and fellowships.

T. MUNGO'S COLLEGE AND GLASGOW ROYAL RMARY.—The classes in St. Mungo's College ify for the medical qualifications of the English, ch, and Irish Conjoint Boards, for the dental omas of the English, Irish, and Scottish Boards under certain conditions, for the various ersities, including the University of London. lents who have fulfilled the conditions of the egie Trust are eligible for the benefits of this st during the whole course of their studies at Mungo's College.

urther particulars can be obtained from a abus which may be procured free on application he Secretary of the Medical Faculty, 86, Castle-et, Glasgow.

OYAL HOSPITAL FOR SICK CHILDREN, St. Vincent-et, Glasgow.—This institution consists of: (1) a ital at Yorkhill containing 275 cots, built on an ated and central site close to the University, and ed in July, 1914; (2) a Dispensary, or Out-ent Department, in West Graham-street, opened October, 1888; and (3) a country branch at mchapel, Dumbartonshire, containing 30 cots, ed in 1903. Children treated must not be over ears of age, nor suffer from infectious diseases. 1927 there were 7143 patients treated in the ls, and the number of attendances of out-patients 83,591. There are one professorship and three ureships in the University of Glasgow in connexion the hospital, one professorship and one lecture-on the Medical Diseases of Infancy and Childhood, lectureship on Surgery and Orthopædics in tion to Infancy and Childhood, and one lectureship io-chemistry in relation to Infancy and Childhood. lectures are both systematic and clinical, but icularly and chiefly the latter. In addition special ities are given for post-graduate study.

ll information may be obtained from the Medical erintendent.

LASGOW ROYAL MATERNITY AND WOMEN'S PITAL, Rottenrow.—114 beds. A Maternity and d Welfare Centre has been established consisting a complete In-door and Out-door Antenatal artment and an Infant Consultation Clinic. A research laboratory is now open. Full par-ars as to fees and accommodation may be ined from the House Superintendent at the ital.

OYAL SAMARITAN HOSPITAL FOR WOMEN, Glasgow. eased to 160 beds by building extensions pleted in 1927. It offers excellent facilities for cal instruction in the diseases peculiar to women. ures and clinical demonstrations are given by bers of the surgical staff to students and to post-uates; and the hospital is represented on the rd of the Glasgow Post-Graduate Medical Associa-tion formed for coördinating post-graduate medical teaching in all the hospitals. The Royal Samaritan Lectureship in Gynæcology is a University Lectureship associated with the Hospital.

For further information, application may be made at the Hospital, or to the Secretary, 149, St. Vincent-street, Glasgow.

GLASGOW LOCK HOSPITAL, 41, Rottenrow, Glasgow. Contains 80 beds for the treatment of females suffering from Venereal Diseases. There is also a Labour Ward, and a well-equipped Dispensary for out-patient attendances. There is a Lecture Room and a Laboratory, equipped with modern appliances, where University classes on the subject are dealt with. Post-graduate classes are also held. Recently the hospital has been completely renovated and modernised. Full information from the Secretary and Treasurer, Mr. J. Neilson Gray, LL.B., 65, Bath-street, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street, and 131, Wellington-street (30 beds and six cots).—This institution is administered by the Royal Infirmary. Clinical and systematic courses of lectures for students during the winter and summer sessions. Operations on Wednesdays and Fridays. Post-graduate classes and demonstrations are arranged during the summer. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine, and by the Royal Colleges of Physicians and Surgeons of England for the Diploma in Ophthalmic Medicine and Surgery. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Post-graduate Classes are held. Secretary and Acting Treasurer, Mr. Harold John Black, 171, West Regent-street, Glasgow.

GLASGOW EAR, NOSE, AND THROAT HOSPITAL, 306, St. Vincent-street (52 beds).—At out-patient and in-door departments clinical instruction is given. Post-graduate Courses are held during the year. Secretary: D. N. Mackay, 144, St. Vincent-street, Glasgow.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., *M.B.*, *Ch.B.*, *M.D.*, *Ch.M.*, a Diploma in Public Health, and Diploma in Dental Surgery (*L.D.S.*).

The extent and standard of the Preliminary Examination is determined by the Scottish Universities Entrance Board constituted under Ordinance No. 70 of the Scottish University Courts (General No. 3—Regulations as to Admission to the Scottish Universities for purposes of graduation), in accordance with the terms of that Ordinance. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities exempts. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years after registering as a medical student. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the

subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz., Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Bacteriology, Practical Chemistry, Physics, Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere with not fewer than 80 patients, with a distinct staff of physicians and surgeons, and recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica, Pathology and Bacteriology, Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

UNIVERSITY COLLEGE, DUNDEE.—The Medical School in St. Andrews University is carried on as follows: In the case of St. Andrews tuition is given only for the first two years, up to and including Physiology and Anatomy. There are no facilities in St. Andrews for clinical studies, but a complete course is given in Dundee from the beginning to the end of the curriculum. Thus it is possible for a student to take his first two years of the curriculum in St. Andrews, transfer to Dundee and complete his course there, or take all his course in Dundee. In either case, the entire curriculum is still in the University. As regards "conjoint medical school," this term seems to refer to the point that in the United College, Dundee, which originally was not an integral part of the University, there was provision made for teaching the first two years of the medical curriculum. Subsequently, Dundee College was affiliated and these original Dundee chairs were included, but the administration of the funds is still retained by the Governors of the United College, Dundee. The remaining chairs in Dundee are financed by the University of St. Andrews. Both the Dundee professors and the St. Andrews professors in Dundee teach in a common building.

ROYAL INFIRMARY, Dundee (461 beds).—In addit to the ordinary Medical and Surgical Wards, there special departments for Midwifery (In- and Out-do for Diseases of Women, of Children, of the Eye, of Ear, Nose, and Throat, and of the Skin; and Clinical Pathology, Radiology, Electrotherapeu and Electrocardiography. An extension provid for a new X Ray Department and Massage Dep ment and for additional Operation Theatre acc modation has been opened recently, a new Mater Department is being built at a cost of £32,000, a new Dispensary at a cost of £25,000. Clin teaching is given to male and female students the Honorary Staff; post-mortem examinations conducted by the pathologists. All courses instruction are recognised by the University of Andrews and the other Universities and Boa of the United Kingdom. Ten Resident Med Officers are appointed every six months. Clin clerks and dressers are attached to the Physici and Surgeons; and Students are appointed assistants in the pathological department. Furt information may be obtained from the Med Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees Medicine and Surgery—viz., *M.D.*, *Ch.M.*, *M.B.*, *Ch.B.* The Degree of Doctor of Philosophy (*Ph.* is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Candidates, bef entering on the curriculum, must have passed Preliminary Examination or hold a qualificat recognised as exempting from such examinati have attained the age of 17, and have passed Pre-registration Examination in Physics Chemistry.

The curriculum for the degrees extends ove period of five years, during which attendance required in the following subjects: Botany, Zoolo Physics, Chemistry (Systematic and Practic Anatomy (Systematic and Practical), Physiol (Systematic and Practical), Materia Medica Therapeutics, Practical Pharmacy, Pathology (S tematic and Practical), Medical Jurisprudence, Pu Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years medical and surgical practice of a recognised hospit they must have attended courses of at least n months in clinical medicine and clinical surge and have acted as clerk in the medical and dresse the surgical wards of a hospital. Attendance required on the practice of a dispensary or the c practice of a hospital and also on courses in Me Diseases, Fevers, Ophthalmology, Post-mortem Exa nations, Venereal Diseases, Tuberculosis, Radiol X Ray, Therapeutics and Electrical Treatment, Clinical Chemistry, and other special subjects. candidate is also required to have been prop instructed in Vaccination and to have attended least 20 Midwifery cases.

Degrees of M.D. and Ch.M.—Candidates for eit of these degrees must already hold the degrees M.B. and Ch.B. of Aberdeen. A thesis (in duplic has to be presented and an examination has to passed in Clinical Medicine (or in some spe Department of Medical Science) or Clinical Surg as the case may be.

Degree of Ph.D.—For this degree candid must pursue a course of special study or rese during a period of nine academical terms as Rese Students in the University of Aberdeen or in College or Institution that may be affiliated ther A Thesis (in duplicate) must be presented for appro

A diploma in Public Health is granted by University to graduates in Medicine of a Univer in the United Kingdom, after a special examinat

Scholarships and Prizes.—In the Faculty of Medi of the University of Aberdeen there are the follow Bursaries, Scholarships, and Prizes:—Bursar about 15 Bursaries (competition and presentati

open each year, of £15 to £30 per annum in value, st of them being tenable for three years. Scholar-os: five Post-graduate Scholarships, value £36 £160 per annum. Prizes and Medals: 15 Gold dals and Prizes for proficiency in special depart-nts.

ABERDEEN ROYAL INFIRMARY (366 beds).—The n clinical work of the students is done in the rmary with its general and special facilities, uding a Department of Clinical Chemistry.

ABERDEEN ROYAL MENTAL HOSPITAL.—This hos-l contains, with hospital attached to main institu-n and agricultural branch, about 950 beds. Clinical ruction is given to students during three nths in summer. Physician-Superintendent, Dr. Dods Brown.

OTHER HOSPITALS.—Students have the opportunity attending the following institutions: City Fever spital, Sick Children's Hospital, General Dispensary, ng-in and Vaccine Institutions, and Ophthalmic itution.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

YAL COLLEGE OF PHYSICIANS OF EDIN-URGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, r one series of examinations, held in Edinburgh or sgow, or both, the student may obtain the diplomas the three bodies. This is the Scottish Conjoint rd.

The three bodies grant their Single Licences only to didates who already possess legal qualifications in licine or Surgery.

The hospitals which are recognised by the Scottish joint Board as places where professional study for ir diplomas can be pursued are all those institutions ch feed the medical faculties of the universities, well as all the places which are recognised by English and Irish Conjoint Boards.

Professional Education.—The candidate must pro-e certificates or other satisfactory evidence of ing attended the following separate and distinct rses of instruction: Physics, three months; mentary Biology, three months; Chemistry, six nths; Practical or Analytical Chemistry, three nths; Anatomy, during at least six months; ctical Anatomy, twelve months; Physiology, months; Practical Physiology, three months; eria Medica, three months; Pathology (including ctical Pathology), nine months; Practice of licine, six months; Clinical Medicine, nine months; ciples and Practice of Surgery, six months; ical Surgery, nine months; Midwifery, three nths; Gynæcology, one course of not less than 13 tings; Diseases of Children, one course of not less n 13 meetings; Medical Jurisprudence and Public lth, three months. The certified attendance on es, demonstrations, and practical work must not less than three-fourths of the total number of -calls. Every student undergoes a course of ctical Midwifery, but before attending at labours s required to attend a course of lectures on Surgery Midwifery and to hold the offices of Clinical lical Clerk and Surgical Dresser. He must also nd for two and a half months' instruction in ctical Pharmacy; the certificate to be signed by teacher, who must be a member of the Pharma-tical Society of Great Britain, or the superintendent he laboratory of a public hospital or dispensary, or gistered practitioner who dispenses medicines to patients, or a teacher of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction, and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital. This attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; Gynæcology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology.

Final Examination.—The Final Examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health; but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical Use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, and Surface Markings.

There are four periods of examination annually.

The Registrar in Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place; and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom particulars of fees can be obtained.

For students registered with the General Medical Council after Jan. 1st, 1923, more extensive Regulations are in force, and candidates applying for Regulations should state date of registration.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards. Special courses of instruction for dental students are also included in the curriculum of this school. The practical classes and laboratories will open and the lectures commence on Oct. 2nd. In

accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school. Post-graduate Courses are conducted in conjunction with the University. Further particulars regarding the school, also its calendar (price 6*d.*) may be had on application to the Dean of the School, Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence.

Fellowship.—The Fellows are selected from the ranks of the *Members*.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College of Surgeons of Edinburgh admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The College grants a diploma of Fellowship after examination to the holders of British surgical degrees or diplomas and the holders of recognised degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire.

The Fellowship.—Candidates must be 25 years of age and in practice for at least two years. The examination is written and viva voce, and includes surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. Candidates are not allowed to appear for more than three times at the examinations. One month's notice of intention to appear for examination must be given by the candidate to the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held separately. The Licence is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may anatomy or physiology or be selected from any spe branch of medicine or surgery. Fourteen days' no must be given by the candidate to the Facu In certain circumstances Fellows may be elected mark of distinction.

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLE (SCHOOL OF PHYSIC).

Matriculation.—University students take Entrance of Trinity College and a Junior Freshr Term or a special Medical Preliminary; Ext Students, any examination recognised by the Gen Medical Council.

Pre-registration Examination in Elementary Phy and Chemistry.—Before beginning the five ye Medical curriculum students must pass an exami tion in elementary Physics and Chemistry. T examination is held at the end of September, January, in March, and in June. Courses preparation for it may be taken in the Schoo Physic.

Degrees in Medicine (*M.B.*), *Surgery* (*B.Ch.*), *Midwifery* (*B.A.O.*).—Candidates for these degr must be of B.A. standing and must be for at least academic years on the books of the Medical Sch reckoned from the date of registration. The course may be taken concurrently with the Med course, and the B.A. degree need not be taken be the final medical examinations, but the Medical deg are not conferred without the Arts degree. The lowing courses must be attended:—(1) Lecture Botany, Zoology, Physics and Practical Phys Systematic, Descriptive and Applied Anator Chemistry and Practical Chemistry; Histol Physiology, Practical and Applied Physiology; P tice of Medicine; Midwifery and Gynæcology, Pa logy and Bacteriology; Materia Medica and Th peutics; Medical Jurisprudence and Hygie Surgery and Operative Surgery; (2) three cou of nine months' attendance on the Clinical l tures of Sir Patrick Dun's or other recogn Hospital; (3) Practical Vaccination, one mon instruction; (4) Mental Disease, three mont (5) Practical Midwifery with Clinical Lectu including not less than 20 personally conduc cases, six months; (6) Ophthalmic Surgery, t months. Three groups of examinations have to passed. Preliminary Scientific Examination, inclu Physics and Chemistry, Botany, and Zoology. Intermediate Medical, Part I., including Anato Physiology, and Organic Chemistry; and Part including Applied Anatomy and Applied Phy logy; and the Final Examination, which is divi into Part I., Materia Medica and Therapeu Hygiene and Jurisprudence, Pathology and Bacte logy; and Part II., Medicine, including Clin Medicine and Mental Diseases; Surgery, inclu Operative and Ophthalmic Surgery; Midwifery Gynæcology. Part I. may be passed in the fou year, and Part II. completed at the end of fifth.

Doctor in Medicine.—A Doctor in Medicine m have passed all the qualifying examinations and mus a B.A. of three years' standing. He must also sub a thesis and pass an Examination before the Re Professor of Physic.

Professional Examinations.—There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognised medical schools at home and abroad. The first examination deals with (*a*) Anatomy, and (*b*) Physiology and Histology. The second examination deals with (*a*) Pathology, (*b*) Materia Medica, Pharmacy, and Therapeutics and Ophthalmology, and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (*a*) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (*b*) Surgery, including Operative Surgery; (*c*) Midwifery, including Diseases of Women and Children, and the Practice of Vaccination.

Diploma in Psychological Medicine.—There are two examinations in connexion with this Diploma: Part I. consists of (*a*) Anatomy and Physiology of the Nervous System; (*b*) Psychology. Part II.: (*a*) Neurology, including Clinical and Pathological Neurology; (*b*) Psychological Medicine, including its legal relationships.

Further information can be obtained from the Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The College issues its Licence in Surgery to practitioners whose names are entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Irish Conjoint Board.

Candidates are examined in General Surgery (paper and oral), Clinical Surgery, Surgical Pathology (oral), Operative Surgery, Surgical Anatomy (paper), and Ophthalmic and Aural Surgery (clinical).

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes Carmichael Scholarship, £15; Mayne Scholarship, £8 Stoney Memorial gold medal; Operative Surger gold and silver medals; Pierefoy Memorial Priz value £150; Barker Prize, £26 5*s.*; H. Macnaughto Jones gold medal in Obstetrics and Gynæcology and class prizes and medals. Prospectuses and guid for medical students can be obtained post free o written application to the Registrar, Royal Colleg of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.*

The Licence of this Hall is granted to students wh present certificates of having fully completed the cours of study as laid down in the curriculum and who pa the necessary examinations. The diploma of th Hall entitles the holder to be registered as a pract tioner in medicine, surgery, and midwifery, with als the privileges of the Apothecary's Licence.

Candidates must pass two Professional Examina tions, called the Primary Examination and the Fin Examination, which are conducted at separate time partly in writing, and partly practically and orall The Primary and Final Professional Examinatio are held twice a year—viz., in June and Novembe or such other dates as may be determined.

Candidates who produce satisfactory evidence having passed an examination for a Degree or Licen in Medicine, conducted by any University or Roy College in the British Empire, or by any Foreig University whose Degrees are recognised in th Foreign List of the Medical Register, will be exempt from the Primary Examination.

The subjects for Part I. of the Primary Examin tion are: Anatomy, Physiology and Histolog including Bio-Chemistry; and for Part II., Mate Medica and Pharmacy, Pathology, and Medic Jurisprudence and Hygiene.

For the Final Examination the subjects ar (*a*) Medicine and Clinical Medicine and Clinic Methods. (*b*) Surgery—Clinical, Ophthalmic an Operative; and Surgical Anatomy. (*c*) Midwifery an Gynæcology, and Practical Pharmacy and Mate Medica (if not taken at Intermediate Examination

Each candidate before receiving his diploma mu produce evidence that he has attained the age of years. The details of the course of education requir and syllabus of the examinations will be suppli by the Registrar at 95, Merrion-square, Dublin.

WE take this opportunity of thanking the offici of Government Departments and the Deans an Secretaries of the various institutions for th kind coöperation in enabling us to bring t information contained in our Students' Number to date.

GUILD OF ST. LUKE.

THE Guild of St. Luke was founded over 60 yea ago by a few medical students, chiefly to meet th own religious needs. It now makes a wider appe and its membership is open to all students an practitioners of medicine, both men and women, wh are members of the Church of England, the cler of which are eligible as Clerical Associates. T Chapter meets in every month of each term, and festival service is held yearly at St. Luke's tid usually at St. Paul's or Westminster Abbey. Th year the service will be at the Abbey. Besides t parent Guild, there are a Women's Ward and Hospital Student's Branch in London. There a also a Midland Counties Ward and a Cambridge War Particulars of the objects and activities of the Gu and forms of application for membership can obtained from the Secretary of the Guild of St. Lul Room B.B., King's College, Strand, W.C.2.

*No returns.

THE LANCET.

LONDON: SATURDAY, AUGUST 25, 1928.

THE READJUSTMENT OF THE MEDICAL CURRICULUM.

DURING the past 12 months no public aspect of ıe calling of medicine has been seriously altered, o legal enactment has introduced any big departure ıto professional life, and no pronouncements of the eneral Medical Council have resulted in any radical ıanges of the curriculum. The tendency in London segregate medical study as between men and omen students may be only a passing phase. The ımbers of the medical profession in practice have emained virtually stable, while the same can be said ı general terms of the population of the Empire, so ıat no situation has been created attributable either an excessive or deficient number of our calling; ıere is still keen competition in some quarters, and ıere is still much room for the right man in others. ut the static conditions do not imply any pause in rogress, for the absence of marked episode has ynchronised with much steady work along educational nes previously laid down.

For example, there may be cited the advance made ıroughout the country towards the readjustment f the medical curriculum in accordance with the esolutions of the General Medical Council passed some x years ago. These resolutions came into force n Jan. 1st, 1923, and their result has been the ccurrence of important deliberations in the Council, ıe various questions arising being dealt with in eports by the Education Committee, and made ıe subject of correspondence between the Committee nd the centres of medical education. The gist f the work of the Council has been to arrange an rderly and common course of study as a minimum tandard for the centres, while safeguarding entry o the profession by an examination ensuring that efore registration the student must have passed recognised examination in general education and, in ddition, an examination in elementary chemistry nd physics either conducted by, or recognised by, ne of the licensing bodies. The registered student ill in this way, theoretically, have broken ground ı two basic directions of his professional work while eing generally equipped up to a professional tandard. After registration the resolutions of he Council in regard to professional education rovide that the period of professional study etween the date of registration as a medical tudent and the date of the final examination for ny diploma entitling to registration should extend ver not less than five academic years. That is o say, the student should have passed the exam-ıation in general education and the pre-registration xamination and have commenced study at a medical chool before he can be registered, after which the ime required is a minimum of five academic years, r, say, 57 months. The proposal for a pre-registration xamination was of course made with the object of ghtening the preliminary portion of the medical ourse, the assistance of various educational agencies, articularly the higher secondary schools, being called ı to assist in laying a scientific foundation for medical tudents. This reform was advocated in our columns nd elsewhere many years ago, but failed to find upport owing to the feeling that the unequal distribution in the kingdom of these secondary schools would act prejudicially for some of the students, but a wider and wiser view now obtains. Other primary and additional resolutions of the Council dealt with the course and examinations of the whole curriculum, suggesting the ground that must be covered by general and special study and the best way in which to allot the time available, when the whole document, in the form of an Interim Report of the Education Committee, was submitted to the various educational centres, who were invited to make comment upon them. They were asked, in fact, to indicate how far their existing patterns of training complied with those advocated by the Council, and the resulting replies disclosed both a satisfactory state of affairs in being and a general willingness to meet the new requirements—this not only in respect of the pre-registration examination and the arrangement of the five years' course, but along many special lines of academic and practical instruction. The replies of the licensing bodies were later published in the Final Report of the Education Committee and the information summarised in this issue of THE LANCET is in accord with them.

Those, then, who are now joining our ranks enter a profession where the steps of their training will be guided with a precision that until quite recently was unknown. This lucid charting of the voyage will be found valuable to many, and indeed to all, for both industry and attention will have to be sustained by them for an extended period. The Council is to be congratulated upon the outcome of delicate and protracted labours in readjusting the curriculum; but it may be pointed out that the whole spirit of these labours, as well as their issue at the present moment, proves that the curriculum will always need readjustment in accordance with the developments of medical science. For example, throughout the latest pourparlers no particular stress appears to have been laid either by the Council or by the licensing bodies on the difficult subject of practical instruction in midwifery, and during the period that has elapsed since the Final Report of the Education Committee on readjustment was published, this question has become burning. Among the various subjects specially recommended for study by the Council, tuberculosis, venereal diseases, and antenatal conditions appeared to the Education Committee to be of particular importance, so much so that, at the request of the Committee, Sir GEORGE NEWMAN prepared a personal report on the subject, which has now been circulated to the licensing bodies. Progress along these lines should help to prevent the sad divergence between preventive and curative medicine. All these licensing bodies provide systematic instruction in midwifery over a fair proportion of the five years' course, and all students are compelled, in addition, to conduct an adequate number of labours within a recognised institution or, under supervision, as clinical visitants at the homes of the patients. But undoubtedly more will be expected. The intentions of all the licensing bodies are admirable, but it is common knowledge that the midwifery training of students, speaking generally, requires strengthening on the practical side. This is a circumstance which will have to be borne in mind when the methods for securing coöperation between the voluntary hospitals and the county institutions are under discussion—as they will immediately be; while the new diploma of the Society of Apothecaries of London demonstrates that a higher standard of obstetric and gynæcological accomplishment is necessary. Midwifery has always been the keystone of general practice.

The Medical Services.

ROYAL NAVAL MEDICAL SERVICE.

Choosing a Career.

To a man of the proper temperament, a career as a medical officer in the Royal Navy offers very definite attractions. In these days his professional knowledge will most certainly not rust in this Service, and in the naval hospitals he will have opportunities of practising every branch of his profession except gynæcology. He can obtain one of 60 paid specialist appointments, and these fall under the headings of medicine; surgery; bacteriology and pathology; hygiene; diseases of eyes, nose, ear, and throat; radiology; anæsthetics; genito-urinary and venereal diseases; and the principles of physical training. He will be encouraged to work hard and will have chances to play hard. The Navy was possibly the first public Service to realise the value of recreation, and puts its provision into practice, and there is no branch of athletics or field sports in which the naval officer does not have an opportunity of engaging in, in a home port or on a foreign station. He will see the world largely and often under ideal conditions. A naval medical officer who is a good doctor, keen on work and play, and unselfish, invariably becomes everybody's friend. The naval officer and the bluejacket are quick to recognise a medical officer who is keen on his work, thoughtful for his patients, and one who strives after improving the health of the Navy. And nowhere can one find more delightful friends than in the Navy.

There is to-day much to encourage the right type of medical man to join the Navy. The Admiralty allow an ante-date of one year to those naval surgeons who before entry held a resident appointment for one year at certain large hospitals, and encourage men to take higher qualifications. Opportunities to this end are freely given, when the exigencies of the Service will permit, and medical officers are able to take post-graduate courses prior to sitting for these higher examinations. As a matter of fact, a large number of naval medical officers since joining the Navy have taken various honour qualifications as well as special diplomas, and it is recognised that this is good for the Navy as well as for the officer. In the large naval hospitals, the medical, surgical, and specialist work is of a high standard. It is exacting, but it is the aim of the Admiralty to arrange appointments as far as possible so that medical officers have an opportunity of alternating their work both at home and abroad, and ashore and afloat. And to give naval surgeons full opportunities for professional work the general and specialist courses have been increased in number so that, as far as possible, every officer shall have a course of instruction of not less than four months' duration every four years. The number of specialists allowed is now 60 instead of 46, and the specialist allowance is 5*s*. a day instead of 2*s*. 6*d*. a day. The establishment of surgeon captains has been increased from 16 to 20.

The total number of medical officers in the Navy is 402, and every recent improvement has been made towards giving increased opportunities of advancement to the best men, in their science, in research, and in organisation. He has opportunities to emulate some of the great naval physicians and surgeons of the past.

Pay.

The cost of living in the Navy is cheap, and an officer can live on his pay and enjoy life if he is not extravagant, especially if he does not embark in matrimony too early. A small amount of private means goes much further in the Navy than in civil life. The three vital points—pay, prospects, and promotion—of the naval medical officer can be grasped by referring to the following clear and brief table.

Full Pay.

	£	£	
Surgeon Lieutenant (short service and permanent service)	from 452	to 499	per annum
Surgeon Lieutenant-Commander (promoted after six years' service)	,, 600	to 636	,,
Surgeon Commander (promoted after a further six years' service)	,, 772	to 976	,,
Surgeon Captain (promoted by selection)	,, 1116	to 1372	,,
Surgeon Rear-Admiral (promoted by selection)	1800		
Medical Director-General (Surgeon Vice-Admiral)	2350		

Allowances.

Allowances when in charge of hospitals and sick-quarters	10*s*. and 5*s*. per diem.
Sixty Specialist allowances of	5*s*. per diem.
Allowances to Senior Medical Officers in flag ships	5*s*. and 2*s*. 6*d*. per diem.

Accelerated promotion can be gained under certain condition there are also, on certain occasions, servant's allowance, provisi allowance, and lodging allowance.

Pension.

	Maximum retired pay.
Surgeon Vice-Admiral	£1123 per annum, on vacati office.
Surgeon Rear-Admiral	£950 per annum, at age of 6
Surgeon Captain	£846 ,, ,,
Surgeon Commander	£564 ,, ,,
Surgeon Lieutenant-Commander and Surgeon Lieutenant	£423 ,, ,,

Gratuities on Retirement.

Below age of 45, officers receive gratuities on retirement on t following scale :—

	£
After 4 years' service	500
,, 8 ,, ,,	1000
,, 12 ,, ,,	1500
,, 18 ,, ,,	2250

The extra allowances alluded to in the table a not to be looked upon as very exceptional. About quarter of the medical officers of the Navy are drawi extra allowances. Of recent years medical office have been admitted into the Navy without entran examination and for short service with the option turning over to the permanent service, but it anticipated that it will not be long before t Admiralty will revert to the old-established syste of entrance by competitive examination twice a ye in batches of about ten officers.

Dental Branch.

The Naval Dental Service offers similar oppo tunities to qualified dental surgeons except th higher rank than that of the recently institut Surgeon Captain (D) is not open to them. Th are provided with suitable surgery accommodati equipped with modern appliances and supplied wi all material required for their work, and there every opportunity for them to maintain a hi standard of professional skill.

Candidates are required to produce certificat of birth, registration, and of character, and must physically fit for active service anywhere. An out allowance of £50 is payable to officers finally enter and commissioned. The rank of Surgeon Lieutenan Commander (D) is attained on the completion of s years' satisfactory service. Promotions to Surge Commander (D) and Surgeon Captain (D) are ma strictly by selection from the rank next below a are confined to officers who prove fitted in eve respect for these ranks. The present establishme of dental officers is: 1 Surgeon Captain (D), 3 Surge Commanders (D), 60 Surgeon Lieutenant-Commande (D) and Surgeon Lieutenants (D).

Provision has been made for candidates wh at the time of passing the examination, hold or a about to hold an appointment as Dental Officer a recognised Civil Hospital. The time concerne provided it does not exceed six months, may reck for increase of full pay while on the active li Surgeon Lieutenant-Commanders (D) of over tw years' seniority will be eligible for a three montl Post-graduate Course while borne on full pay.

As in the case of the medical branch, 20 per cent. f the rates of full pay, unemployed pay, half pay, and tired pay introduced in 1919 is considered as due to ie high cost of living in 1919 and subject to change eriodically either upwards or downwards according s the cost of living rises or falls. The first revision ook place in July, 1924, when all the rates were educed by approximately 5½ per cent., the second evision took place in July, 1927, when all rates ere reduced by ½ per cent., and further revisions re due every three years—i.e., in July, 1930, and o on.

ARMY MEDICAL SERVICE.

Royal Army Medical Corps.

The publication of the Royal Warrant of 1926 has moved many of the grievances of officers of the orps, and this Service can again be recommended a career to young medical men. Competitive aminations for regular commission, which have een in abeyance for some time, will again be held alf-yearly in January and July. These examinations medicine and surgery are entirely of a clinical and actical character, partly written and partly oral.

The regulations for admission giving full details ould be obtained from the Permanent Under ecretary of State (A.M.D. 1), War Office, Whitehall, ondon, S.W. 1, and carefully studied. A personal terview with a representative of the Director-General, rmy Medical Services, is readily obtainable.

The rates of pay and allowances are good; the portunities of post-graduate study are generous, id the work is varied, responsible, and interesting. he gratuities after certain periods of service enable officer should he so desire to leave the Service with capital sum large enough to go a long way towards -establishing himself in civil life, and, further, the nowledge of the world and the comradeship of his llow officers that he has gained in the Army will be no small value to him.

New entrants are commissioned in the rank of eutenant, and the first six months of service are ent on probation, during which time they undergo, addition to their Military training at the Royal rmy Medical Corps Depôt at Aldershot, a pro- tionary course at the Royal Army Medical College London in Hygiene, Pathology, Tropical Medicine, ilitary Surgery, Recruiting, the prevention and eatment of Venereal Disease, and the elements of rmy Administration. At the end of this course, id after qualifying at the necessary examinations, their commissions are confirmed, and they take their places in seniority according to the total marks obtained at all examinations up to that date. Officers Training Corps service with possession of Certificates "A" or "B" (Medical) carry a definite value in marks in this total.

An entrant who is holding or about to hold at the time of the entrance examination a resident House Appointment at an approved Civil Hospital may be seconded while holding such an appointment up to a maximum period of 12 months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to 12 months in respect of the period the appointment was held. This secondment and antedate counts in all respects as commissioned service, except that pay will not be issued for that period.

After a total period of one year's service at home the young officer goes abroad, probably to India, for his first tour of foreign service. Here he gains his first practical experience of tropical disease and tropical hygiene, and possibly his first experience of active service on the frontiers of India. His tour abroad lasts five years, with probably six months' leave home during that time. On returning home the R.A.M.C. officer has the opportunity to decide whether he will remain in the Corps or accept the gratuity of £1000 after seven years' service, and try his fortune in civil life. If he elects to remain, he will, between his eighth and twelfth year of service, undergo a course of post-graduate study at the Royal Army Medical College and the London Hospitals of five months' duration, followed by a course of study of a special subject selected by himself, provided he has shown special aptitude in the post-graduate course or during his previous service. During this period of study he remains on full pay, and the fees for the courses are paid by the State. When qualified in his special subject, the officer becomes entitled to specialist pay at 5*s.* per day when holding a specialist appointment. After this post-graduate course the officer probably proceeds abroad again and promotion to Major rapidly ensues, and from that time onward the officer receives regular successive increases of pay, and is eligible for additional and charge pay as well. The Directorates of Hygiene and Pathology and the appointment of two serving officers as Consultants in Medicine and Surgery have been instituted and have proved a marked success, all these appointments being of the rank of Colonel or Major-General.

Under these conditions the possibilities for good workers are very great in the Royal Army Medical Corps. There is scope for original research in tropical

* Pay Warrant rates as amended by A.O. 196/26 less 6 per cent. from July 1st, 1927, vide A.O. of 1927. The Pay Warrant rates are subject to revision to an extent not exceeding 20 per cent. according to variation in the cost of living. The next revision takes place from July 1st, 1930.

† Rates of allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations.

disease, in preventive medicine, and in bacteriology, as well as in the large clinical field open to the specialist in Medicine, Surgery or Gynæcology, in Venereal Disease, and in Ophthalmology. Child welfare is also undertaken systematically by officers of the Royal Army Medical Corps.

At the same time instruction in administration is continuous. The Royal Army Medical Corps is essentially organised for war, and one of the lessons of the Great War was that trained administrators must exist to enable the fullest benefit to be obtained from professional talent. Many appointments carrying administrative responsibility are open to those officers who display capacity for this duty. All officers must be prepared to undertake command and to have a knowledge of Army administration, especially in war. Equally important is the technical training of the Non-commissioned Officers and men of the Corps in such "trades" as Trained Nurse, Nursing Orderly, Masseur, Radiographer, Operating Room Assistant, Laboratory Assistant, Hospital Cook, Dispenser, &c. This training is carried out by the Officers and Nursing Sisters, and opens a large field for those who have ability in lecturing and teaching as well as the power of influencing men.

Promotion.

Promotion takes place automatically to Captain after 3½ years, and to Major after 12 years' service, provided the officer is qualified and recommended for promotion. Promotion to the higher ranks is by selection from those senior in the rank below, but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps.

Additional Pay and Charge Pay for R.A.M.C. Officers.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under.

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology, and Venereal Disease. Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 5*s.* daily.

(2) (*a*) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds	2*s.* 6*d.* daily.	300 beds	7*s.* 6*d.* daily.
150 „	5*s.* 0*d.* „	500 „	10*s.* 0*d.* „

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates.

	Daily. s.	d.
(*b*) Senior medical officer, Royal Arsenal, not exceeding	10	0
(*c*) Officer in command of the depôt, Royal Army Medical Corps	5	0
(*d*) The senior officer of the Army Medical Services with an army in the field: A rate to be fixed by the Army Council according to the magnitude of the charge.		
(*e*) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5	0
(*f*) Adjutant R.A.M.C. Depôt	5	0
(*g*) Adjutant R.A.M.C. (Territorial Army)	2	6

Retirement and Retired Pay.

The following are the rates of pension and retired pay:—

1. Retired pay will consist of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible for retired pay.

2. The scale will be as follows, subject to the reduction of 6 per cent. referred to below:—

(*a*) Service element.—£15 a year for each completed year of service as a medical officer.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant-Colonel	150	30	240
Colonel	290	50	390
Major-General ..	440	50	540
Lieutenant-General	590	50	690

The retired pay of an officer retiring with less than or complete year's service in the rank from which he retires wi be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together:—

	£		£
Captain and Subaltern ..	300	Colonel	80
Major	450	Major-General ..	100
Lieutenant-Colonel ..	600	Lieutenant-General	120

The above rates are those laid down in the Pay Warran They have been reduced by approximately 6 per cent. from July 1st, 1927, and are subject to future variatio with fluctuation in the cost of living.

3. Officers with seven and less than 20 years' service medical officers may be permitted to retire with a gratuity accordance with the following scale:—

After 7 years' service as a medical officer	£10
„ 15 „ „ „ ..	£28
„ 18 „ „ „ ..	£35

THE ARMY DENTAL CORPS.

The Corps is administered by the Director-Genera Army Medical Services. It is a joint service for th Army and Royal Air Force, and personnel is require to serve under either force and be interchangeabl Officers and other ranks posted for duty with th Royal Air Force will perform their duties under th Regulations of the Royal Air Force for the emplo ment of dental personnel, but the conditions in th following tables apply equally in either force. Pr motion is carried out on one general list. Regulatio for admission to the Army Dental Corps should obtained from the Under-Secretary of State, W Office, and carefully studied.

OFFICERS: *Appointment and Promotion.*

1. Commissions as Lieutenants in the Army Dental Cor may be given to persons duly qualified under regulatio approved by the Army Council.

2. An officer shall be eligible for promotion to the rank Captain on completion of three and a half years' service and the rank of Major on completion of 12 years' service in t Corps, provided he has previously qualified in such manr as may be prescribed by the Army Council.

3. Promotion to the rank of Lieutenant-Colonel a Colonel to fill the establishments laid down from time to ti for those ranks shall be made by selection of the Arr Council, provided the officer has previously qualified promotion to those ranks in such manner as may be p scribed by the Army Council.

4. Appointments are in the rank of Lieutenant, except cases where service of three and a half years or more has be given as a temporary dental officer, when the rank of Capt will be given. Service as a temporary dental officer v count towards the three and a half years for promotion captain, and the 12 years for promotion to Major.

Pay.

The following are the rates for officers of the Army Den Corps:—

	Per die £	s.
Lieutenant	0	18
Captain	1	3
Captain { after 8 years' total service	1	6
„ 10 „ „ „	1	8
Major	1	12
Major, after 15 years' total service	1	17
„ „ 18 „ „ „	2	0
„ „ 20 „ „ „	2	4
Lieutenant-Colonel	2	11
Lieutenant-Colonel after 3 years' service as such	2	16
Colonel	3	3

These rates are 6 per cent. below those shown in Pay Warrant, 1926, as amended by Army Order 196

e latter are subject to revision to an extent not exceeding per cent., according to variation in the cost of living. e next revision takes place on July 1st, 1930.

Charge Pay.

The officer in charge of the Dental Laboratories, Aldershot, eives charge pay at the rate of 5*s.* a day if holding the rank Captain, or 2*s.* 6*d.* a day if holding the rank of Major.

Allowances.

The allowances for officers of the Army Dental Corps are the same rates as for officers of the Royal Army Medical ps.

Retirement and Retired Pay or Gratuity.

1) The rates of retired pay will be the same as for officers he Royal Army Medical Corps.

2) Voluntary retirement on retired pay will not be allowed il after twenty years' service.

3) Earlier retirement on gratuity may be allowed :—

After 8½ years'	service as a Dental	gratuity of	£1000.
,, 15 ,,	Officer,	,,	£2000.
,, 18 ,,		,,	£3000.

The aim of the Corps is the prevention of wastage man power on account of dental disease or dental iciency, and, to enable this to be carried out, every ruit is inspected by a dental officer immediately er joining and all necessary treatment carried out. e soldier is re-inspected at least once a year and dental efficiency maintained at the best standard ssible. As recruits are not now enlisted unless y have sufficient natural teeth to enable them masticate efficiently, it is hoped that the conserva- e nature of the treatment they will receive will luce considerably the percentage of artificial tures required.

INDIAN MEDICAL SERVICE.

It is the view of many senior officers in the Service t the period of depression is now passing and that prospect is again bright for those who are fitted physique and disposition for a medical career in lia. The offer of permanent commissions on cially favourable terms to a small number of dical men of European descent who were free to l forthwith to India met last year with the desired ponse, and the number of commissions granted ring the last twelve months is 16.

But the new outlook involves frank acceptance of Indian reform scheme, the essential of which is reasing participation of Indian-born subjects in government of the country, although, so long as ropeans are employed in the various departments the Indian Civil Service, nothing is more certain n that there will and must remain European tors to attend them. India definitely requires ropean assistance, not only for the care of the litary and civil European population, but for the intenance in the country of that spirit of modern dicine which has accomplished already such ghty things, and which day by day is spreading influence and value.

The Government of India issued a communiqué ly this year dealing in detail with the reorganisation the medical services in India. The scheme now ctioned is based on proposals framed in consultation h local governments. The Indian Medical Service, stituted on the same broad lines as at present, will retained primarily to meet the needs of the Indian ny, and in order to maintain two essential requisites namely, (1) the necessary minimum war reserve of dical officers, and (2) the provision for European dical attendance on officers and their families. cal governments in India will be required to employ stated number of I.M.S. officers. It has been culated that the war reserve to be employed by the il side should consist of 134 British and 66 Indian cers, the larger proportion of British officers being e to the fact that they cannot be recruited on ergency in India from the ranks of private practi- ners. Medical attendance on British personnel, and the requirements of civil administration, for which the Central Government is still responsible, involve the provision of a number of employments termed "residuary," the incumbents of which must be retained permanently in civil employment, so as to ensure the continuance under any circumstances of a skeleton staff to cope with civil requirements. The total number of officers required for civil employment in the I.M.S. is now calculated at 302, allotted as follows: war reserve, 200; residuary posts in provinces, 46; foreign and political departments, 17; gaols, 8; special posts under the Government of India, 14; port health officers at Bombay and Aden, 2; reserve of 5 per cent. as allowance for illness, 15. Of this total 212 will be European and 90 Indian. To provide employment for these 302 officers, 237 posts are required, 59 of which will be available under the Government of India, and 178 (of which 112 must be held by British officers) will be provided in the provinces. The estimate of the medical requirements of European medical attendance is based on data which will change from year to year as the proportion of European to Indian civil officers diminishes; it will therefore be subject to scrutiny and revision. The remaining 66 posts will be open either to Europeans or Indians, while 28 out of 59 appointments under the Government of India will similarly be open to officers of either race.

Rules forming an integral part of the reorganisation scheme have been drawn up to safeguard the varied interests of the Indian army, the provincial governments, and the medical officers themselves (vide THE LANCET, May 19th, 1928, p. 1028).

Thus the social effect of Indianisation should not press hardly on the medical service for the reason that European doctors will be chiefly requisitioned in stations with considerable European communities. In these communities the equipment and organisation of hospitals has been steadily improving and men with professional ambition will find positions which will satisfy their aspirations. On the military side the station hospital system has rendered the position of medical officers more independent by making teamwork possible and permitting of specialisation in various departments of medicine and surgery. Lastly, those who join now will have unequalled prospect of advancement in a Service which has been so depleted for 10 or 15 years or more, and the terms of service announced by the Secretary of State for India in 1926 assure conditions of pay, pension, and furlough much superior to those previously offered.

The New Regulations.

Competitive examination remains suspended for the present and admission to the Service is on written application to the India Office. As sound bodily health is a first essential candidates may, if they wish it, undergo a preliminary examination by a Medical Board which meets weekly at the India Office.

Candidates must be under 32 years of age at the time of application, and must possess a qualification registered in Great Britain and Northern Ireland, under the Medical Acts in force at the time of appointment. Arising out of the recommendations of the Lee Commission the Secretary of State for India in Council after consultation with the Government of India has decided that the Indian Medical Service constituted on the same broad lines as in the past shall be retained primarily to meet the needs of the Indian Army. In order to maintain the necessary minimum war reserve of military medical officers, and to provide for European medical attendance for European officers of the Superior Civil Services and their families, local governments will be required to employ a stated number of Indian Medical Service officers. The Government of India will draw on the same Service to meet the requirements of the civil administration for which they are responsible. For the present 237 such posts have been reserved, and including the leave reserve will provide employment

for 302 officers. 212 of these officers will be British medical men and 90 Indians. As the proportion of European to Indian civil officers diminishes these figures will be subject to periodical scrutiny, and, if necessary, to revision. It will be a definite condition of service for all future entrants to the Service that they will be liable to serve on either the civil or the military side. All officers are required to perform two years' military duty subsequent to permanent appointment before they can be considered eligible for civil employment. Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it. On the military side, however, the opportunities for private practice are not great. Service during the war as a medical or combatant officer, or in a position usually filled by an officer, counts towards promotion and pension so long as the rights of officers who have entered by competition are not interfered with.

Rates of Pay.

The monthly rates of pay for European officers of non-Asiatic domicile in the Service are as tabulated below. The rupee, it may be remembered, has now been definitely stabilised at 1*s.* 6*d.*

Rank and service in rank.	Basic pay.	Overseas pay.	Year of total service.
	Rs.	Rs.	
Lieut.	500	150	First
		150	Second
		150	Third
Captain :—			
1. During first three years' service as Captain.	650	150	Fourth
		£15	Fifth
		£15	Sixth
2. With more than three and less than six years' service as Captain.	750	£25	Seventh
		£25	Eighth
		£25	Ninth
3. With more than six years' service as Captain.	850	£25	Tenth
		£25	Eleventh
		£30	Twelfth
Major :—			
1. During first three years' service as Major	950		
2. With more than three and less than six years' service as Major	1100		
3. With more than six years' service as Major.	1250		
Lieut.-Colonel :—			
1. Until completion of 23 years' total service	1500	£30	Thirteenth and over.
2. During twenty-fourth and twenty-fifth years' total service	1600		
3. After completion of 25 years' total service	1700		
4. When selected for increased pay ..	1850		

Note.—Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1) which, owing to the system of accelerated promotion, may be in advance of the time-scale of promotion. Overseas pay is regulated solely with reference to length of total service (column 4). In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the I.M.S. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service. The appointment of Director-General, I.M.S., which is held by an I.M.S. officer, carries pay of Rs.3500 per mensem. The appointment of Director of Medical Services in India, carrying pay at Rs.3200 per mensem, may also be held by an officer of the Indian Medical Service.

Initial rates of pay are based on the assumption that the majority of newly appointed officers will be bachelors. An officer, when junior, is liable to more frequent changes of station than later on in his service, and he may therefore be put to considerable expense for transfers if he has a family. Officers who are married before joining may find difficulty in living within their pay during the first few years of their service. Officers in military employment, when in command or second-in-command of the larger station hospitals, receive special allowance. On the civil side there are public health, bacteriological research, and professorial appointments carrying special enhanced rates. Officers on appointment receive an outfit allowance of £50.

Pensions and Allowances.

The rates of pensions are as shown in the table below.

Service.	Rates per annum.	Service.	Rates per annum
After 17 years ..	£400	After 23 years ..	£620
„ 18 „ ..	430	„ 24 „ ..	660
„ 19 „ ..	460	„ 25 „ ..	700
„ 20 „ ..	500	„ 26 „ ..	750
„ 21 „ ..	540	„ 27 „ ..	800
„ 22 „ ..	580		

Note.—The above rates are subject to revision triennially upwards or downwards, to an extent not exceeding 20 per cent. in all, on account of a rise or fall in the cost of living, compared with the year 1919. A deduction of 4½ per cent. on this account has already been made. Nevertheless the full pension of a lieutenant-colonel cannot be cut below the maximum of £700 under the old rules in the case of officers who entered the service before July 1st, 1920.

There are additional pensions not subject to the above reduction ranging from £65 to £350 per annum for officers who have held high administrative appointments as colonels or major-generals.

Officers on appointment are provided with free passage to India, normally by transport. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be given free passage to India. Officers are granted a certain number of return passages home at Government expense during their career. There are special allowances for officers whilst on study leave.

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall, London, S.W. 1. Letters should be marked "Recruitment for I.M.S."

ROYAL AIR FORCE MEDICAL SERVICE

THE Air Council attach great importance to attracting into the Service the best type of medical man since on the capacity of the Medical Service depends in a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the Service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely scientific as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop talents for administration.

The work to be done, therefore, has a high professional interest which, combined with good rates of pay and allowances, offers a career for medical men which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation.

His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

The establishment will consist partly of permanent d partly of short-service officers.

An officer will on first entry be granted a short-rvice commission for a period of three years on the tive list (which may be extended to five years at e discretion of the Air Council if the officer so shes on the recommendation of the Director of edical Services) and of four years in the Reserve of r Force Officers. Selections for permanent com-ssions will be made from officers holding short-rvice commissions, and those who are not ected will be transferred to the Reserve at the piration of their period of service on the active t.

For those entrants who desire it the prospect of taining a permanent commission is approximately within establishment to the rank of Wing Commander will be by selection at any period after 16 years' total service, and that of Group Captain by selection at any period after 22 years' service.

Certain posts in these ranks are reserved for officers fully employed in professional work, such as surgery, pathology, ophthalmology, &c., numbering at present six in all. The number of these posts will be limited only by the needs of the Service and by the necessity of observing a similar proportion between the number of reserved posts and the officers from whom they can be filled, as exists between the total number of higher ranks and the remainder of the medical service. Selections for these reserved posts will be made only from officers professionally qualified to hold them. Officers filling the reserved posts will be

* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at rates d subject to conditions authorised from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light, rations, and personal attendance are not available kind. Normally, provision in kind is available for junior officers. "Married" rates of allowances are payable only to married icers who have reached the age of 30 or the rank of Squadron Leader. A colonial allowance is granted in certain commands road. The rates and general scheme of allowances are liable to revision as circumstances may require.

even one. Experience has so far shown that the ficers selected have included the great majority of ose desirous of, and suitable for, retention in the rvice; owing to the fact that the short-service mmission with its gratuity after three or five years in itself an attraction to many entrants who desire enlarge their experience and outlook from the int of view of subsequently entering private practice, who, on entry, have not made up their minds to e adoption of a permanent career in the Service and bsequently find that they would prefer to return civil life.

For certain purposes medical officers may be lowed to count as service their time spent in sident appointments in civil hospitals under certain ll-defined and generous conditions.

Officers who have been selected for permanent mmissions may be permitted to attend for a period t exceeding nine months a post-graduate course general medicine and surgery, tropical and preven-ve medicine, and other special subjects. Such rmission may be granted at any time when the igencies of the Service permit during the first years of service, and when attending these courses ficers will receive full pay and allowances.

New entrants into the Royal Air Force Medical rvice will be commissioned as Flying Officers ledical) and will be eligible for promotion to the nk of Flight Lieutenant (Medical) after two years' rvice. Officers selected for permanent commissions ill normally be promoted to the rank of Squadron ader after ten years' total service. Accelerated omotion may be granted in a limited number of ses to officers who show exceptional ability after e completion of eight years' service. Promotion eligible for selection to the administrative appoint-ments of their rank, and to the highest administrative appointments.

There will be no competitive examination on entry; candidates must be under 28 years of age, be British subjects, the sons of British subjects, and of pure European descent, be nominated by the dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce:—

1. Birth certificate. 2. Medical registration certificate. 3. A declaration containing the following information: (*a*) Age and place of birth. (*b*) That he is a British subject, the son of British subjects, and of pure European descent. (*c*) That he is ready to engage for general service at home or abroad as required. (*d*) The qualifications he is possessed of, and what medical or other appointments he has held (if any). (*e*) That he is willing to fly as a passenger whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants will undergo an initial course of eight weeks, during which they will be given instruction in the special medical aspects of aviation, the organisation and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch.

In order to avoid the necessity for further examinations the position of entrants in order of seniority

in the Air Force List will be determined at the end of the initial course by a system of marking and reports on the actual work done during their instruction.

Uniform and Equipment.

Medical officers are required to provide themselves with the uniform, service dress, and mess dress of their rank and with the distinguishing badges of the Royal Air Force Medical Branch. The provision of full dress is entirely optional at present. An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces.

Emoluments.

The emoluments of medical officers of the Royal Air Force are given in outline above. The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919, and 20 per cent. of each of the standard rates is detachable and subject to alteration either upwards or downwards as the cost of living rises or falls. Under this provision the current rates now in force represent a reduction of approximately 6 per cent. on the standard rates. The next revision will take effect from July 1st, 1930, and subsequent revisions will be made at intervals of three years.

RETIRED PAY.

The minimum period of service qualifying for retirement on retired pay is 20 years. Standard rates of retired pay are as follows:—

Air Officers.

Air Vice-Marshal .. .. £790 to £1010 per annum.
Air Commodore .. .. £650 „ £950 „ „

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are:—

Rank.	Yearly rate of retired pay.	Compulsory retiring age.
	£	
Air Vice-Marshal ..	1010	60
Air Commodore ..	950	57
Group Captain.. ..	900	55
Wing Commander ..	600	51
Squadron Leader ..	500	48

Retired Pay of Officers below Air Rank.

Age on retirement.	Standard yearly rate of retired pay.	Years of service.	Addition for each extra year of service.*	Deduction for each deficient year of service.*
	£		£	£
40	300	17	15	15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15

53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

* Limited to five years.

Gratuities.—A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service, namely:—

£1500 if he has 10 but less than 15 years' commissioned service.
£2500 „ 15 or more than 15 „ „ „

Short-service officers will be eligible on passing to the Reserve for gratuities on the following scale: £100 for each of the first two complete years of service, £150 for each of the third and fourth complete years and £200 for the fifth complete year; that is:—

For three years' service on the active list .. £350
For five „ „ „ „ .. £700

These gratuities will not be payable to officers granted permanent commissions, but their service on a short service commission will count towards retired pay.

COLONIAL MEDICAL SERVICE.

IN the self-governing Dominions (Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland), and territories under their control, such as Papua and the Cook Islands and in the self-governing colony of Southern Rhodesia, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; in North Borneo application should be made to the British North Borneo Company, 17, St. Helen's-place, E.C., for appointments; and those in Sarawak are in the hands of H.H. the Rajah. Much valuable information will be found in the "Professional Handbook," Part II., issued by the Oversea Settlement Office, Caxton House, Tothill-street, London, S.W. 1, price 9*d*.

As a general rule, each Colony or Protectorate has its own public service distinct from that of every other; and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another. There are three exceptions to this rule: (*a*) The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, is one service. (*b*) The East African Medical Service, which serves Kenya, Uganda, Zanzibar, Nyasaland, Somaliland, and the Tanganyika Territory is one service. (*c*) In practice the medical services of the Straits Settlements and the Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States or vice versa; the two services are now called the Malayan Medical Service.

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the Secretary of State for the Colonies are (*a*) the West African—viz., Nigeria, the Gold Coast, Sierra Leone, and the Gambia, with the Mandated Territories of Togoland and the Cameroons; (*b*) the East African—viz., the Kenya Colony and Protectorate, Uganda, Nyasaland, Somaliland, and Zanzibar Protectorate; the Tanganyika Territory, and Northern Rhodesia; (*c*) the Eastern—viz., Ceylon, the Straits Settlements and Malay States, Hong-Kong, Mauritius, and Seychelles; (*d*) the West Indian—viz., Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, and the Bahamas; (*e*) Fiji and the Western Pacific, Cyprus, Gibraltar, St. Helena, British Guiana, British Honduras, Bermuda, and the Falkland Islands; and (*f*) Palestine.

In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. In the Bechuanaland Protectorate, Basutoland, and Swaziland appointments are usually filled locally. Appointments in Malta are all filled locally. In addition, certain medical appointments in the service of the Government of Iraq are filled with the concurrence, and normally upon the recommendation, of the Secretary of State. Vacancies occur most regularly and frequently in the West African Medical Staff, the East African Medical Service, and the Straits Settlements and Malay States.

All applicants for medical appointments in the gift of the Secretary of State for the Colonies should be under 35 years of age, and must be doubly qualified; preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and pro

sional competence will be required, and every icer before being definitely appointed will be dically examined by one of the consulting ysicians of the Colonial Office: Sir William Prout, M.G., O.B.E., and Dr. A. E. Horn, C.M.G., 104, urley-street, London, W. 1; Major-General J. J. rrard, C.B., C.M.G., the Royal Hospital, Kingsdge, Dublin; Dr. Foster Coates, 22, College-dens, Belfast; and Lieut.-Colonel Glen Liston, .E., I.M.S., 33, Comely Bank, Edinburgh, and . C. V. Le Fanu, 33, Rodney-street, Liverpool. pplications for such appointments must be addressed the Private Secretary (Appointments), Colonial fice, 2, Richmond-terrace, Whitehall, S.W. 1.

East African Medical Service.

The Medical staffs of the Kenya Colony and otectorate, the Uganda, Nyasaland, Somaliland, d Zanzibar Protectorates, and the Tanganyika rritory form one service, the members of which e liable to be posted or transferred to any of the pendencies as the exigencies of the service may quire. The preferences of individual officers are, wever, taken into consideration as far as possible. Selected candidates are appointed as medical icers on probation in the first instance for two ars, at the end of which period their appointnts are made permanent if their service has en satisfactory. Unless the Secretary of State rects to the contrary, they are required to tend a course of instruction at the London Liverpool School of Tropical Medicine or the iversity of Edinburgh before taking up their ppointments. If such a course is not taken fore proceeding to East Africa, they are required take it during their first leave of absence. edical officers (but not sanitation officers) are rmitted to take private practice at some stations the understanding that they give precedence to eir official duties. It must be understood that ditions to their income from this source are not ely to be substantial, and that the privilege is ble to withdrawal at any time.

Officers are provided with quarters free of rent or e Government may provide temporary accommodaon, or an allowance in lieu of quarters may be paid. ie salary of a medical or sanitation officer is £600 r annum, rising by annual increment of £30 to 40, and thence by increments of £40 to £920, bject to an efficiency bar at £840. Senior medical ficers and senior sanitation officers are paid on the ale £1000 by annual increments of £50 to £1100. fficers who possess the Diploma in Public Health entering, or who acquire it while in the Service, ceive two special increments in the scale.

Officers of the East African Medical Service are rmitted to retire with gratuity, if they wish, instead waiting to retire on pension as follows: (*a*) After ne years' service, of which at least six must have en spent in East Africa, £1000; (*b*) after 12 years' rvice, of which at least eight must have been spent East Africa, £1250. If an officer elects to retire th gratuity he thereby forgoes all claim to nsion.

The grades and salaries (apart from ordinary edical and sanitation officers) in the medical departents are as follows:—

Kenya.—Director of Medical and Sanitary Services, 500; Deputy Director of Medical Service, £1200; Deputy rector of Sanitary Service, £1200; Deputy Director of aboratory Service, £1200.

Uganda.—As Kenya.

Tanganyika Territory.—As Kenya.

Nyasaland.—Director of Medical and Sanitary Services, 200; Medical Entomologist, £1000–£50–£1100.

Zanzibar.—Director of Medical and Sanitary Services, 400; Deputy Director of Sanitary Service, £1200: Resint Surgical Officer, £1000–£50–£1100.

Somaliland.—Principal Medical Officer, £1000–£50–£1100.

There are also the following posts:— Resident rgical Officers (Kenya and Uganda), £1200; pecialist Officer, Sleeping Sickness (Uganda), £1150; Medical Superintendent and Principal of Medical School, Mulago Hospital (Uganda), £1150; Sleeping Sickness Officer (Tanganyika Territory), £1000–£50–£1100; Senior Bacteriologists (Kenya and Uganda), £1000–£50–£1100.

Sanitation officers are selected from the ranks of medical officers as occasion arises.

Asia.

Straits Settlements and Federated Malay States.—European medical officers are appointed on the following scale of salaries: $500 per mensem, rising to $550 per mensem during three years' probation; then, if they are placed on the pensionable establishment, rising to $575 per mensem, and thence by annual increments of $25 per mensem to $800 per mensem, with a strict efficiency bar at $600 per mensem. Officers possessing the D.P.H. receive an additional allowance (non-pensionable) of $100 per mensem.

Above the concluding figure of $800 per mensem there are certain higher appointments, as follows: Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $1200 per mensem; Director, Institute for Medical Research, Federated Malay States, Chief Health Officer, Federated Malay States, and Principal Medical College, Straits Settlements, $1100 per mensem; Senior Surgeon, Singapore, $1050 per mensem; 3 Chief Surgeons, Federated Malay States, $1000 per mensem; Medical Officer and Ophthalmic Surgeon, $1000 per mensem; 6 posts at $1050 per mensem; and 17 posts at $850 per mensem, rising annually by $30 to $1000 per mensem. There are also 14 medical appointments, including several senior posts, in the Unfederated Malay States.

The following temporary allowances are at present paid to all officers recruited from Europe in the Government Services of the Straits Settlements and Federated Malay States: unmarried officers, 10 per cent. of salary; married officers, 20 per cent. of salary. Private practice by Government medical officers is not allowed, but consultation work with another practitioner is permitted. Information about general conditions in Malaya is obtainable from the Malay States Information Agency, 57, Charing Cross, S.W. 1.

Seychelles.—The chief medical officer receives Rs.7000 per annum. There are four assistant Government medical officers, two receiving Rs.6500, the others Rs.3000 per annum.

Hong-Kong.—The present establishment of the medical department is: director of medical and sanitary services, £1200–£50–£1450; deputy director, £1125–£25–£1200; senior medical officer, £1025–£25–£1100; three medical officers of health, £740–£30–£1040; health officer of the port, and second health officer of the port, £740–£30–£1040; five medical officers, £600–£30–£1020; bacteriologist, £800–£1100; assistant bacteriologist, £740–£30–£1040; radiologist, £740–£30–£1040; analyst, £625–£25–£900; assistant analyst, £400–£25–£700. A temporary allowance on a scale varying with the sterling exchange value of the dollar is at present payable. Salaries are converted locally at the rate of 2*s.* = $1. Free quarters are not provided, but in certain instances a rent allowance is paid by the Government.

America.

British Guiana.—There are the following posts in the medical service of the Colony: one surgeon-general, £1000–£1200 per annum, with consulting practice; one medical officer of health, £900; ophthalmologist, £700; one bacteriologist and pathologist, £700; 37 medical officers at £500–£25–£700. Most of the senior posts in institutions carry duty allowances (varying from £50 to £300 per annum) and quarters.

Trinidad and Tobago.—In Trinidad and Tobago there are about 40 appointments. Government medical officers receive salary at the rate of £400

per annum, rising by annual increments of £25 to £600. An officer appointed to a district receives, in addition to his salary, a travelling allowance varying from £100 per annum in a normal district to £150 per annum, and is allowed private practice, the value of which is estimated at from £50 to £800 per annum. Officers employed in institution work receive a duty allowance varying from £50 to £300. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent). There are over 25 appointments. The chief medical officer, Grenada, receives £750. The chief medical officer, St. Lucia, receives £600–£700 plus forage and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government are on the scale from £400–£500, except in St. Vincent, where the maximum is £450. The Governor has the power to transfer a medical officer from one island to another. Appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The appointments are similar in number and character to those in the Windward Islands, and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £350, and is later appointed to a definite district at a salary varying from £312 to £400–£25–£450, and the Governor decides as to the district which is to be allotted to him, according to station. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands. The medical officers, except in St. Christopher and Nevis, receive fees for successful vaccinations, post-mortem examinations, evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also, as a rule, allowed private practice. The chief medical officer, St. Christopher and Nevis, receives £700–£25–£750, but is not allowed private practice, except as a consultant.

British Honduras.—There are seven medical appointments (besides the post of principal medical officer) at a salary of $2430 per annum with increments of $120 to $3150. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The value of the dollar is the same as that of the United States dollar.

Other Overseas Appointments.

Fiji.—The Chief Medical Officer receives £1000–£50–£1100, with free quarters, unfurnished; the Medical Superintendent, Colonial War Memorial Hospital, £800–£50–£1000, with £40 car allowance and free quarters; the Medical Superintendent, Leper Asylum, £750–£50–£950, with completely furnished quarters and one servant; the Medical Officer of Health, £750–£25–£900, no quarters provided. There are 14 District Medical Officers who receive £500–£25–£725, with partly furnished quarters or £50 house allowance (at the option of the Government) and duty allowance of £50 per annum in districts where no private practice exists. In certain districts house allowances or car allowances are granted. In others a medical officer is provided with a launch or boat. District Medical Officers are allowed private practice on the understanding that their official duties are not neglected. In five districts the Medical Officer is also District Commissioner and receives an additional allowance of from £175 to £275 and free partly-furnished quarters. In most districts there is private practice, the value of which has been estimated at from £100 to £600 a year.

Western Pacific High Commission.—The staff in the British Solomon Islands Protectorate consists of a Senior Medical Officer (£650–£750), two District Medical Officers (£550–£650), and one Travelli Medical Officer (£550–£650). Partly-furnished qu ters are provided and a local allowance of £50 annum is paid to the Senior Medical Officer and t District Medical Officers. A local allowance of £ consolidated travelling and subsistence allowar £200, and partly-furnished quarters are provided the Travelling Medical Officer.

In the Gilbert and Ellice Islands Colony there a Senior Medical Officer (£650–£750), with part furnished quarters, and one Medical Officer (£60 £25–£650), with partly-furnished quarters or ho allowance. There is hardly any private pract in the British Solomon Islands Protectorate or t Gilbert and Ellice Islands Colony.

Cyprus.—There is a chief medical officer paid at t rate of £750, rising by annual increments of £25 £850, and three district medical officers paid at t rate of £500 a year, rising by annual increments of £ to £600 a year, all enjoying private practice (exce the chief medical officer and one of the distr medical officers, who are allowed consulting pract only). There is also a post of consulting surge £400–£20–£600 a year, with consulting practi There is also a medical officer of health on £6 rising by £20 increments to £750 without priv practice, and a specialist in venereal diseases wit salary of £700 a year and consulting practice; th are the only medical appointments open to Brit candidates.

Gibraltar.—There is a surgeon of the Colon Hospital receiving £730, and private practice. Th are also two assistant surgeons with a salary of £6 for 3 years and thereafter £650–£25–£700 per annu who are allowed private consulting practice on Free quarters, unfurnished, are provided for all th officers.

St. Helena.—The colonial surgeon at pres receives £550 per annum, fees estimated at about £ a year, and £30 horse allowance. The assistant colon surgeon at present receives £500 a year and £30 ho allowance. Private practice is allowed, and su practice, together with the duties of non-Governm appointments, is divided between the colonial surge and the assistant colonial surgeon in a proporti approved by the Governor. The value of priv practice and appointments is estimated at ab £536 a year.

Falkland Islands.—There are two appointmen The colonial surgeon is paid at the rate of £600 annum, with free furnished quarters. The assist colonial surgeon is paid at the rate of £500 per annu with an allowance of £50 per annum in lieu of quarte Private practice is shared between the colonial surge and the assistant colonial surgeon. The office colonial surgeon is pensionable. The medical serv of this colony is now under review.

Palestine.[1]—The grades and salaries of hig appointments in the Department of Health a Director, £P.1200, plus £P.200 expatriation allowan Deputy Director, £P.900–50–£P.1100, plus £P.1 expatriation allowance. Assistant Director (Labo tories), Specialist Surgeon,[2] and five Senior Medi Officers, £P.750–25–950, plus £P.100 expatriati allowance. One Senior Medical Officer and Gove ment Analyst, £P.550–25–750, plus £P.100 expatr tion allowance. The remainder of the staff recruited locally. A temporary and variable cost-living allowance is at present payable in addition the salaries stated above.

Iraq.—The grades and salaries of the princi appointments in the Department of Health a Inspector-General of Health, Rs.1800–100–2800 month; Health Specialists, Directors of Hospit and Institutes, Chief Medical Officers in Mosul a Kirkuk, Medical Officers of Health in Baghdad a Basra, Rs.1500–75–1800–100–2300 a month; Medi Officers, Rs.1200–75–1800 a month. Posts in t

[1] £P.1 = £1 sterling.
[2] A certain amount of private practice is allowed.

ice of the Government of Iraq are not pensionable. ry officer (unless serving on a 3 years' contract) quired to contribute one-twelfth of his pay to a ident fund, to which the Government makes a ribution equal to one-sixth of his pay.

Leave and Pensions.

eave and Passages.—Leave of absence in East ca. The normal tour of service is 20 to 30 ths (less in Somaliland) after which leave is ted with full salary for 2½ to 3½ days, according he districts in which the officer has served, for month of service, plus the period of the voyage England. If the officer is returning to East ca for further service, he receives a further similar unt of leave, plus the period of the voyage to t Africa. Extensions of leave with full salary given in case of sickness or in the case of officers nding approved courses of instruction. In ition to the above, local leave may be granted to 14 days a year. Officers serving in Northern desia are allowed four (or two) days' leave in ect of each month of service. Free first-class ages are provided for the officer on first appoint- t and on leave, and in certain cases assistance ards family passages is given.

the Malay Peninsula two months' leave of absence full salary may be granted in respect of each 's service, and this leave may be accumulated up maximum of eight months. Additional leave on -pay may be granted on special grounds. Officers provided with free passages on first appointment themselves and their families (i.e., wife and lren up to five persons, inclusive of the officer). er temporary regulations at present in force, return passages on leave to all officers (and their s and their children under the age of 10) irrespec- of salary.

other Colonies outside Tropical Africa, subject he necessities of the service, leave of absence on salary may be granted after a period of three s' resident service without any special grounds. ay be given before the expiration of that period in of serious indisposition, or of urgent private rs. In the absence of special grounds, the leave t not exceed one-sixth of the officer's resident ice; on special grounds it may exceed that period ix months. In addition to the above, vacation e on full pay may be granted, if no inconvenience xpense is caused thereby, not exceeding three ths[3] in any two years. British Guiana, Jamaica, Trinidad officers are allowed to accumulate pay leave at the rate of six weeks for each year's ice up to six months, exclusive of the period of voyages to and fro, and no leave of absence (except in very special circumstances) exceed months in all unless the officer has served for years or more without leave, in which case two ths on half-pay may be taken in addition to months' full-pay leave.

n first appointment an officer will, except in case of a few Colonies possessing Representative mblies, be provided by the Crown Agents for the nies with free passages to the Colony for himself his wife and children, if any, not exceeding four ons besides himself. The officer so appointed be required to execute an agreement binding him pay the cost of the passage or passages so obtained e event of his leaving the Government service in three years. An officer taking leave out of Colony has in most cases to provide his own ages.

nsions.—East Africa.—Officers on the pension- establishment may retire (or be retired by Government) on attaining the age of 50 years; they may be retained in the service, with their consent, for such further period as the Govern- t may recommend. Earlier retirement in the t of ill-health is also provided for. Pension is computed at one-four hundred and eightieth of pensionable emoluments—i.e., salary and value of free quarters [4] in respect of each month's pensionable service—at the time of retirement, subject to an average of emoluments for the last three years before retirement instead of the actual emoluments at the time of retirement being taken as the basis for calculation in certain circumstances.

Other Colonies.—In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half-pay as half service. In a few cases the retiring age is 60 and the pension after ten years' service is ten-sixtieths instead of fifteen. In the Straits Settlements and Malay States, an officer may, with the consent of Government, retire at age 50. Pensions are calculated on a basis of length of service in months instead of years.

West African Medical Staff.

Applicants for appointment as medical officers or medical officers of health in the West African Medical Staff (the higher grades will usually be filled by promotion from the lower) must be British subjects of European parentage and between 23 and 35 years of age; preference is given to candidates who are over 25 years of age. Applicants must possess a complete double qualification, and must be on the Medical Register. Passages for wives and children are not provided by the Government, and houses for the wives of junior medical officers are rarely available. Officers are not usually allowed to take their wives and young children out with them until they have acquired experience of the local conditions and have obtained the sanction of the Governor. When an officer has obtained permission to be accompanied by his wife a grant of one-half the cost of his wife's passage to and from West Africa is made subject to certain conditions.

Candidates whom it is proposed to select for appointment will have to be medically examined by one of the medical advisers of the Colonial Office (or, in the case of those residing in a Colony, by a medical officer appointed by the Colonial Government), and no appointment will be made unless the candidate is declared to be physically fit for service in West Africa. Candidates are allowed to express a preference for any particular Colony, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony at the discretion of the Secretary of State. Candidates who wish to be posted to Nigeria will probably find it useful to be able to ride. Transfers from one Colony to another will be made as seldom as possible. Candidates should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred.

Those transferred to pensionable Crown appointments elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided that they have been members of the staff for at least 12 months. Every officer selected for appointment is required to have himself revaccinated before proceeding to West Africa, unless one of the medical advisers of the Colonial Office certifies that this is unnecessary.

[3] or, in the case of Fiji and the Western Pacific and the and Islands 4½ months in any three years.

[4] The value of free quarters for pension purposes is taken as 15 per cent. of the minimum salary of the grade in which an officer is serving at the time of retirement, subject to a maximum of £150.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction either at the London School of Hygiene and Tropical Medicine, Endsleigh-gardens, N.W. 1, or at the Liverpool School of Tropical Medicine, Liverpool University, or at Edinburgh University. The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £25 a month will be paid to them monthly in arrear while they are under instruction. Payment of the allowance will be made subject to the candidate signing an agreement by which he is bound to refund it (1) if he declines to accept an appointment in any of the Colonies for which he may be selected; (2) if he fails to obtain a certificate or diploma; (3) if he relinquishes the Service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of his arrival in West Africa.

If at the end of the session there exists no vacancy in the Staff to which a candidate can be appointed, he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy.

Leave of Absence.—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony. Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa. An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances; and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service within the above limits, the actual length of each officer's tour will be at the discretion of the Governor. Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months.

Appointments and Salaries.—Medical officers for the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria (Southern and Northern Provinces)—are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. The grades and emoluments of the Staff are at present as follows:—

The Director of the Medical and Sanitary Service, Nigeria, receives a salary of £1800 a year, with a duty allowance at the rate of £360 a year. The Director of Medical and Sanitary Service in the Gold Coast receives a salary of £1600 a year, with a duty allowance at the rate of £320 a year. The Director of Medical and Sanitary Service in Sierra Leone receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year. The Deputy Director of Medical and Sanitary Service, Nigeria, and the Deputy Director of Sanitary Service, Nigeria, receive salaries of £1500 a year, with duty allowances at the rate of £300 a year. The Deputy Director of Medical and Sanitary Service, Gold Coast, and the Assistant Director of Medical and Sanitary Services, Nigeria, receive salaries of £1400 a year, with duty allowances at the rate of £280 a year. Assistant Directors Medical Service: There are seven appointments on this grade, five in Nigeria, two in the Gold Coast. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. The Assistant Director of Sanitary Service, Nigeria, the Deputy Director of Sanitary Service in the Gold Coast and the Deputy Director of Sanitary Service in Sierra Leone receive salary at the rate of £1300 a year, with duty allowance at the rate of £260 a year. Specialists: The number of these appointments is not fixed, officers of outstanding professional merit being eligible for appointme The salary is at the rate of £1300 a year, with du allowance at the rate of £260 a year. After f years' approved service as such, the specialist offi is eligible to receive a salary at the rate of £1400 a y with duty allowance at the rate of £280 a year. T are at present five officers appointed specialists in Nig three in the Gold Coast, and one in Sierra Leone. Se Medical Officer: There are twenty appointments of t grade, with salary at the rate of £1000 a year, rising annual increments of £50 to £1150 a year, and senior allowance at the rate of £100 a year. The Senior Medi Officer, Gambia, is allowed "staff pay" of £150 a year, addition to duty allowance, but he is debarred from priv practice. Senior Sanitary Officer: There are nine appoi ments of this grade, with salary at the rate of £1050 a ye rising by annual increments of £50 to £1200 a year, and duty allowance at the rate of £210 a year. Possession of Diploma in Public Health is usually required for appoi ment to this grade. Special facilities are granted to study the diploma during leave. Medical Officers of Healt There are at present 24 appointments of this grade. T salary scale is the same as that of Medical Officers, exc that Medical Officers of Health are granted an ini salary at the rate of £800 a year, together with senio allowance at the rate of £72 a year and staff pay at rate of £150 a year, half of which is payable during lea After three years' service on the maximum of the sc viz., £960 a year, and on undergoing an approved cours study, Medical Officers of Health are eligible, if unpromot subject to the recommendation of the Governor, to be pla on the scale £1000 a year rising by annual increments £50 to £1150 a year, together with seniority allowance the rate of £100 a year and staff pay as before. The hold of these appointments are not allowed private pract Candidates selected for service as Medical Officers of Hea must obtain the Diploma in Tropical Medicine and Hygi of Cambridge, London, or Liverpool as a condition of appo ment, or must be in possession of the Diploma in Pul Health. They are appointed subject to the condition th if after a period of service in West Africa they are conside unsuitable to serve in that capacity, they may be called u to transfer to the medical side. In such cases the offi are given the rate of salary which they would have reac if they had been appointed to be Medical Officers instead Medical Officers of Health in the first instance. Med Officer: The salary attached to this grade is at the rate of £ a year, rising by annual increments of £30 to £720 a y Then, if confirmed in the appointment, £720 a year, rising annual increments of £40 to £960, with seniority allowanc the rate of £72 a year. Before passing £800, medical offi are required to take a special course of study for three mon If they obtain satisfactory certificates at the end of course they draw their further increments up to £960 a y

A medical officer who has served for three years the maximum salary of this scale (£960) with obtaining promotion is eligible, if recommended the Governor, to be placed on the scale £1000–£ £1150, with £100 seniority allowance (as for Se Medical Officers).

Special Appointments.—The Director of the Medi Research Institute, Lagos, and the Director the Medical Research Institute, Accra, receive a sal of £1300 a year, with a duty allowance of £26 year, rising after five years' approved service t salary at the rate of £1400 a year and duty allowa at the rate of £280 a year. There are a number appointments for pathologists and bacteriologists Nigeria and the Gold Coast. The salary and ot conditions attached to these posts are similar to th of Medical Officers of Health. Duty allowan seniority allowance, and staff pay are not pensiona emoluments.

Increments.—Increments to salaries are pay only when the service of an officer during the pe of employment qualifying for increment is approv

Payment of Salaries.—Information as to the p ment of officers' salaries or of monthly remittance persons in England may be obtained from the Cr Agents for the Colonies, 4, Millbank, S.W. 1. allowances are paid locally.

All officers of the staff, except directors, dep directors, assistant directors, senior sanitary offic medical officers of health, research officers, an few other officers holding special appointme are at present allowed to take private pract provided that it does not interfere with the fait

d efficient performance of their official duties, but is within the power of the Governor to withdraw suspend the privilege in such places and for ch periods as he may consider desirable. Private actice does not exist at many stations, and no arantee can be given that an officer will be posted a station in which he will be able to practise ivately. As a general rule, and subject to the igencies of the service, stations where there is private actice are allocated to senior members of the Staff.

Pensions and Gratuities.—Pensions and gratuities on tirement are granted in accordance with the law and gulations of each individual Colony.

Fuller information can be obtained from the Private cretary, Colonial Office, 2, Richmond-terrace, ndon, S.W.1.

Sudan Medical Service.

This Service is responsible for carrying out civil, edical, and public health duties in the Sudan.

The staff consists of: (*a*) A Director, pay £1500–000. (*b*) A Senior Physician and a Senior Surgeon the Khartoum and Omdurman Civil Hospitals, ch with a pay of £1200–£1750. (*c*) An Assistant irector and Medical Officer of Health, Khartoum ovince, pay £1200–£1750. (This latter post is mporary, and the terms and duties are subject to teration). (*d*) 31 British "Senior Medical Inspectors" and "Medical Inspectors," whose pay comences at £720 and rises, subject to the recommendaon of the Director, by five biennial increases to 080, and after 13 years' service to £1200. The nior Medical Inspectors are eligible, by selection, r the four senior posts. All Medical Inspectors are ppointed, in the first place, on probation for two ars, and if at the end of that time they are accepted r permanent service under the Sudan Government, e first increase of pay is subject to their passing examination in Arabic.

In addition to the above there are (*e*) a number Medical Officers trained at one of the Syrian edical Schools, besides (*f*) Sudanese Medical Officers ained at the School of Medicine at Khartoum. here are several native (*g*) Assistant Medical Officers, ho have been given a purely practical training in ne of the larger hospitals in the Sudan.

Amongst the attractions of the Service are: The eat variety of the work met with among many fferent races of the Sudan; *leave* of 90 days, hich is granted every year after the first 18 months service; *study-leave*, which may be given for some finite purpose, whilst two years towards pensionable rvice may be granted to those who have special ualifications and experience. The pension for edical Inspectors who retire after 20 years' service not less than £E.500 a year. If, however, he rves for a longer period, or is appointed to one of ne higher posts, he will receive a larger pension. rivate practice is allowed, but is limited to a few the larger towns, and may be carried on so long s it does not interfere, in any way, with official uties. These duties include acting as consultant the principal hospitals and the supervision of edical and public health work, the inspection of hools, the examination of candidates for Government rvice and pension, and the training of Assistant edical Officers and native Sanitary Overseers. he Khartoum Medical School is staffed, mainly by embers of the Medical Service, who receive an dditional remuneration of £250 a year for their ork as teachers. A Registrar of the Medical School also selected from the Service, who receives £250 a ar extra pay.

The country is developing rapidly, and the Medical epartment is being increased to meet its growing quirements. Vacancies are always advertised in HE LANCET as they occur.

Candidates must be single and under 30 years f age, and they must have held a resident post, referably that of house surgeon, in a large general ospital. As a rule they are required to take out a ourse in Tropical Medicine before they leave England for the Sudan. The fees for this course are paid by the Sudan Government, and in addition, an allowance of £4 15*s.* per week is made, under certain circumstances, to each selected candidate who attends it.

Inquiries for further information should be made to Dr. Acland, 19, Bryanston-square, London, W. 1, or to the Deans of the principal medical schools.

WOMEN'S MEDICAL SERVICE FOR INDIA.

Among careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. This service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 44. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals. Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare; medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Rates of pay are as follows:—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	English equivalent* per annum.
1 to 3	Rs.100	Rs.450	£440
4 to 6	„	Rs.500	£480
7 to 9	„	Rs.550	£520
10 to 12	„	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600
16 to 18	„	Rs.700	£640
19 to 21	„	Rs.750	£680
22 to 24	„	Rs.800	£720
over 24	„	Rs.850	£760

* At rupee value 1*s.* 4*d.*

Furnished quarters are provided, representing an additional Rs.150 per mensem.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.200 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years. Study-leave on two-thirds pay is granted to the extent of 12 months in the total service. There is a provident fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent., which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Major-General J. B. Smith, India Office, Whitehall, London.

SPECIAL DIPLOMAS.

DIPLOMA IN TROPICAL MEDICINE.

ALTHOUGH a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Hygiene and Tropical Medicine, 23, Endsleigh-gardens, Euston-road, N.W.; while the Universities of Cambridge, London, Edinburgh, and the English Conjoint Board grant the diploma.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (*University of London*).—The Departments of Bacteriology and Immunology under Prof. Topley, and of Epidemiology and Vital Statistics under Prof. Greenwood, will continue their advanced courses of study in October next, the Bacteriology course (covering the new Diploma) at 6, Gordon-square, W.C., and the Epidemiology course at the National Institute for Medical Research at Hampstead. The existing Departments of the School dealing with the courses of study for Tropical Medicine and Hygiene will continue for the present in the building occupied by the Hospital for Tropical Diseases at Endsleigh-gardens. There are two such courses in the year, each lasting 20 weeks, inclusive of examinations. The dates for the commencement of each course are Oct. 1st, 1928, and March 11th, 1929, respectively. The course covers the work required for the D.T.M. and H. (England) and part of that required for the M.D. in Tropical Medicine of the University of London. For facilities for clinical and pathological study the School is indebted to the Seamen's Hospital Society, who, prior to August 1st, 1924, were responsible for the London School of Tropical Medicine. The new building in which the School will be housed is approaching completion, and the formal opening and the commencement of the new courses of study (in particular that of the D.P.H.) will probably be in the summer or autumn of next year. Research studentships and scholarships are available, and full particulars with regard to these and the courses of study generally may be obtained from the Secretary of the School, Malet-street, London, W.C. 1.

University of Liverpool.—The University grants a Diploma in Tropical Medicine. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The subjects of examination are (*a*) Tropical Pathology, Tropical Parasitology; (*b*) Entomology; (*c*) Tropical Hygiene and Sanitation; (*d*) Tropical Medicine, including Ætiology, Symptoms, Diagnosis, and Treatment of Tropical Diseases. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. Applications should be made to the Dean of the Medical Faculty, University of Liverpool.

The University also grants a diploma in Tropical Hygiene (D.T.H.). The subjects of examination are Bacteriology, Chemistry (including Meteorology and Climatology), Parasitology and Entomology, Tropical Sanitation (including Sanitary Engineering), Practical Sanitation, Sanitary Engineering, Statistics. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

University of Cambridge.—The examination for the Diploma in Tropical Medicine and Hygiene is divided into two parts. Part I. is held in Cambridge in April and Part II. in July in London. Candidates for Part I. are examined under the same regulation and in the same subjects as candidates for the Diplom in Public Health, but any qualification in medicin or surgery recognised by the proper authority of an country outside the British Dominions may b recognised. The subjects for Part II. are Medicin Surgery, and Hygiene in their relation to Tropica Disease.

The examination will be partly in writing, partl oral, and partly practical or clinical (the clinica part will be conducted at a hospital for tropica diseases, at which cases will be submitted for diagnos and comment). Every candidate who passes th examination to the satisfaction of the examiners wi receive from the University a diploma (D.T.M. & H testifying to his knowledge and skill in tropica medicine and hygiene.

Further information respecting the courses of stud and examinations may be obtained from Mr. J. Purvis, Public Health Chemical Laboratory, Can bridge.

University of Edinburgh.—Candidates for th Diploma in Tropical Medicine and Hygiene mus be graduates in medicine and surgery of the Universit of Edinburgh or hold corresponding registrab degrees or qualifications of some other licensin body. The course of instruction, comprising primary and a second course, is given during th autumn and spring terms, October to March, an includes Tropical Hygiene, Bacteriology, Entomolog and Parasitology, Diseases of Tropical Climat (systematic and clinical), Tuberculosis, and Venere Diseases. The primary course alone is also give during the summer term, April to June. Provisio is made in the University for instruction in all subject The examinations are written, oral, and practica and are held at the end of the courses. Candidat are required on the first occasion of presentin themselves for examination to appear for all th subjects. Candidates who fail to pass the enti examination within a period of 12 months after fir appearance are required to reappear for all th subjects. The University is included in the list Institutions whose courses of instruction in Tropic Medicine may be taken by officers on appointmen to the Colonial Medical Services or during study-leav Full particulars can be obtained from the Dean the Faculty of Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—Th diploma of D.T.M. & H. Eng. is awarded on th results of an examination held twice yearly, February and July. Candidates must possess registrable qualification, and produce evidence having attended (1) practical instruction in patholog protozoology, helminthology, entomology, bacteri logy, and hygiene in relation to tropical medicine a recognised institution during not less than fi months; (2) clinical practice of a recognised hospit for the same period. Conditions of study may b modified in the case of candidates of special experienc Notice of entry to the Secretary, Examination Ha Queen-square, London, W.C.1.

DIPLOMA IN BACTERIOLOGY.

The University of London has instituted a academic diploma in bacteriology, and a full tim course covering this diploma will be given October by the London School of Hygiene an Tropical Medicine. This course will be held a 6, Gordon-square, London, W.C. 1, pending th opening of the new buildings behind the Britis Museum which are now under construction. Th diploma is open to graduates in medicine, science, pharmacy of London or of any other approve university. Registered medical practitioners or oth non-graduate students who have obtained a quali cation and undergone a previous training which in th opinion of the University has fitted them to profit b the instruction may be admitted. The course study, which extends over an academic year,

ided into two parts, of which the first is concerned h bacteriological principles and with general hnique. The second part of the course is to be oted to bacteriology applied to (1) clinical medicine, hygiene, or (3) industry, at the selection of the ndidate.

Public Health: Epidemiology and Vital Statistics.—course in Epidemiology and Vital Statistics is vided by the London School of Hygiene and pical Medicine, under Prof. Greenwood, at the tional Institute for Medical Research, Hampstead. ference is given to medical graduates, and students not normally be admitted for a course of less than ee months.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Universities of Cambridge, London, Durham, eds, Manchester, Edinburgh, Dublin, National iversity of Ireland, and the Conjoint Board of R.C.P. Lond. and R.C.S.Eng. now grant diplomas psychological medicine under conditions that are rly comparable in the standard of the tests and in duration of the courses; the details on these nts can be obtained from the various examination dies.

In London, courses of instruction for the Diploma Psychological Medicine are given annually at the udsley Hospital, Denmark Hill, which has recently n definitely recognised as a school of the University London. The course consists of two parts, mmencing in January, and is adapted for the loma of the Conjoint Board, the University of ndon, or the University of Cambridge. The parts y be taken separately; also during the year there other short courses, lectures and demonstrations psychological medicine.

Maudsley Hospital.—Appointments as clinical assistts are obtainable at the Maudsley Hospital. The lding of such appointments for varying periods isfies the requirements of the different examining dies in respect of practical study of mental disorders. e appointments and other facilities for clinical perience are open to qualified medical practitioners art from the courses of instruction. Inquiries as lectures should be addressed to the Director of the ntral Pathological Laboratory, Maudsley Hospital, nmark Hill, S.E.; and as to clinical facilities, to Medical Superintendent at the same address.

Bethlem Royal Hospital.—A course of lectures and ctical instruction for the Diploma in Psychoical Medicine, granted by the various universities d the Conjoint Board, is held at Bethlem Royal spital, London, S.E., twice annually, during spring and autumn. The fee for the full course 15 guineas. Part A or Part B, however, may be en separately at a fee of 10 guineas per part. addition to the above, clinical instruction in ychological Medicine is given at Bethlem Royal spital every morning (except Wednesdays) at 11 A.M. e fee for students is 3 guineas for a period of ee months' attendance and for post-graduates a of 5 guineas for a like period. A reduction is de to those who attend the Diploma Course. use physicians are appointed at Bethlem Royal spital for a term of six months, which may be ended. These appointments are made on May 1st d Nov. 1st in each year and the vacancies are vertised in the medical papers. Apartments, comte board, attendance, and laundry are provided and o a salary at the rate of £100 per annum. Clinical istants are often appointed from time to time for riods of three months or longer. These are nonaried and non-resident posts, but partial board provided. The Physician-Superintendent, Bethlem yal Hospital, will supply further particulars.

University of Edinburgh.—Candidates for the ploma in Psychiatry must be graduates in medicine d surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. Candidates are required subsequent to the date of graduation or obtaining a registrable qualification to have held (*a*) a resident appointment for one year in a hospital for mental disorders approved by the Faculty of Medicine, or alternatively (*b*) a six months' appointment as defined in (*a*) and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty of Medicine. There are two examinations for the Diploma. Part I. comprises 1. Anatomy of the Nervous System. 2. Physiology of the Nervous System. 3. Psychology and Experimental Psychology. Part II. comprises: 1. Neuropathology. 2. Clinical Psychiatry. 3. Clinical Neurology. 4. An additional subject selected by the candidate from a prescribed list. The examinations are held twice yearly in March and July. Candidates who have held an asylum appointment for a period of five years or more may be exempted from the course of study in one or more subjects of the curriculum. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Dublin University.—A post-graduate diploma in Psychological Medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognised institution for the treatment of Mental Diseases for 12 months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Candidates must also attend special courses of instruction and pass a special examination. Details can be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

The National University of Ireland and the *Conjoint Board of the Royal Colleges of Ireland** confer a diploma in Psychological Medicine upon similar terms; application should be made to the Registrar of the School of Physic and the Secretary of the Board respectively.

DIPLOMA IN OPHTHALMIC MEDICINE.

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.—The diploma in ophthalmology (D.O.) is granted to registered medical practitioners after passing an examination, held annually in March, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course. Further information regarding these requirements may be obtained from the Dean of the School of Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in February and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a registrable diploma or a Degree in Medicine and Surgery of a University recognised by the Board.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

University of Cambridge.—The D.M.R.E. is open only to those who have held for at least one year a medical qualification approved by the Committee. The new regulations, which come into operation this year, in some respects materially alter the scope of

* No returns.

the Diploma. The course now occupies nine months, beginning in October. The first three months, which can be spent either in Cambridge or in London, are occupied with lectures and practical work in Physics in preparation for the examination for Part I. in January, and an introductory course in Radiology and Electrology. The second three months must be spent in London. The course includes lectures and clinical instruction in Radiology and Electrology, with clinical practice in the radiological department of a hospital approved for that purpose by the Committee. The examination for Part II. is held in April. During the final three months a candidate must hold a clinical clerkship or similar appointment in a radiological department approved by the Committee, and must then present a thesis in the form of a critical report with notes upon six cases either in Radiology or in Electrology or in both these subjects, illustrating various methods of diagnosis or treatment. A number of large provincial hospitals have been approved by the Committee to take clinical assistants for this part of the course.

Further particulars as to courses and examinations may be obtained from G. Stead, M.A., Cavendish Laboratory, Cambridge, or from Dr. Stanley Melville, British Institute of Radiology, 32, Welbeck-street, London, W. 1.

University of Liverpool.—Candidates before admission to the examination for this diploma must possess a registrable qualification, approved by the University in medicine and surgery, and must have attended courses of instruction in (*a*) physics (two terms), (*b*) (i) radiology, and (ii) electrology during six months in the X ray and electrotherapeutic departments of a hospital or hospitals. An examination is held in March each year, the subjects being (*a*) physics, (*b*) radiology and electrology. Examination in either part may be taken separately. Fees: tuition, £24 5*s*.; examination and diploma, £6 5*s*. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

University of Edinburgh.—Candidates for the Diploma in Radiology (D.R. Univ. Edin.) must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualification from some other licensing body. Candidates are not admitted to the examination for the Diploma until after the lapse of not less than one year from obtaining a registrable qualification, which qualification must be registered before admission to the Examination. The course of study begins in October and extends over a period of not less than three terms. The Examination, which is written, oral, and practical, is in two parts: (*a*) Physics, and (*b*) Radiology. The Examination is held twice yearly —viz., July and October. Full particulars may be obtained from the Dean of the Faculty of Medicine.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

The Conjoint Board R.C.P. Lond., R.C.S. Eng., grants the D.L.O. after an examination held in two parts, twice yearly, in June and December. Part I. comprises anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus. Part II. comprises the medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus, and the recognition and use of special instruments and appliances. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of one year of special study of the diseases of the ear, nose, pharynx, and larynx, after obtaining a registrable qualification, or a degree in medicine and surgery of a University recognised by the Board. The fee for admission to each part is 6 guineas.

DIPLOMA IN TUBERCULOUS DISEASES.

A Diploma in Tuberculous Diseases is given by t University of Wales. Candidates must possess medical qualification registrable for practice in Gre Britain and Ireland, and be not less than 25 years age, and either (Category A) have held, for a peri of not less than five years, whole-time appointmen for work in tuberculosis; or (Category B) have he a registrable qualification to practise for at least o year, and presented (*a*) a certificate of satisfacto pursuance of a course of consecutive post-gradua study of the clinical and epidemiological aspects tuberculosis of six months' duration at a recognis university, medical school, or hospital where su a course is given; or, alternatively, a certificate one year's post-graduate work as a whole-time memb of the staff of a tuberculosis hospital, sanatorium, dispensary approved by the Ministry of Health, sign by the representative of the authorities for whom t work was performed or by the administrative medic officer concerned; (*b*) a certificate of satisfacto pursuance of a course of consecutive post-gradua practical study of the Pathology and Bacteriology Tuberculosis of three months' duration at a tuberc losis laboratory or a recognised general laborato where such a course is given; (*c*) a certificate of thr months' satisfactory attendance at a tuberculo institute or dispensary.

The examination is divided into two parts and t fee is £10 10*s*. Applications should be made to t Registrar of the University, University Regist Cathays Park, Cardiff, not later than May 15 The above regulations apply up to and includi the next examination, to be held in June, 19 New regulations, particulars of which may be obtain on application to the Registrar, will come into fo for 1930.

The Cecil Prosser Research Scholarship, of the val of £250 for one year, is awarded triennially for resea in Tuberculosis.

DIPLOMA IN PUBLIC HEALTH.

THE following epitomises the instruction given various universities and centres of medical educati to medical men desiring to obtain diplomas in sanita science, public health, hygiene or State medici as this discipline is variously called. Resolutio designed with a view of ensuring "the possession o distinctively high proficiency, scientific and practic in all the branches of study which concern the pub health," have been adopted at various times by t General Medical Council. The diploma is registra by the Council, whose rules on the curriculum beco binding on the educational bodies concerned. T new regulations, which came into force in 19 extend the period of study and postpone the granti of a diploma until at least two years from qualificati

Conjoint Board of the R.C.P. Lond. and R.C.S. E New regulations came into force on Jan. 1 1924, which apply to all candidates who have n commenced bona-fide study of Public Health accordance with the above regulations before th date. They are as follows: The Examinat consists of two Parts. Part I. will be held in months of January, April, and June, and Part II. the months of January, April, and July in each ye Candidates may enter for Parts I. and II. separat or at the same time, but they must pass Part I. bef proceeding to Part II. The Examination in ea part will be written, oral, and practical. Part will include a practical examination in Infecti Diseases, Food Inspection, and Inspection of selec Premises. Candidates who fail to satisfy the Examin in either part may present themselves again at t next Examination on payment of the same fe Candidates intending to present themselves for eit part of the Examination must give 14 days' notice writing to the Secretary, at the Examination H Queen-square, London, W.C. 1.

Candidates will be admissible to Examination in rt I. on producing evidence :—

1. Of being in possession of a registrable qualification in dicine, Surgery, and Midwifery.

2. Of having attended during a period of not less than e months at an Institution recognised by the Examining ard in England, practical instruction in (*a*) Bacteriology d Parasitology (including Medical Entomology) especially their relation to diseases of man and to those diseases of e lower animals which are transmissible to man, during 0 hours, of which not less than 150 hours have been cupied in practical laboratory work. (*b*) Chemistry and ysics in relation to public health, during 90 hours, of ich not less than 70 hours have been occupied in practical oratory work. (*c*) Meteorology and Climatology in ation to public health, during not less than 10 hours.

Candidates will be admitted to Part II. of the xamination on producing evidence :—

1. Of having been in possession of a registrable qualifica- n in Medicine, Surgery, and Midwifery during not less an two years, of being registered by the General Medical uncil, and of having completed the curriculum for the ploma extending over a period of 12 calendar months bsequent to the attainment of a registrable qualification.

2. Of having attended, after obtaining the registrable alification, instruction during not less than 80 hours at Institution recognised by the Examining Board in gland in the following subjects :—(*a*) The Principles of blic Health and Sanitation for not less than 30 hours ;) Epidemiology and Vital Statistics for not less than hours ; (*c*) Sanitary Law and Administration (including blic Medical Services) during not less than 20 hours ;) Sanitary Construction and Planning during not less than hours.

3. Of having attended for three months the clinical prac- e of a hospital for infectious diseases recognised by the xamining Board in England and of having therein received struction in the methods of administration. The certificate ust state that the candidate has attended on one or more ys in each week of the three months, that each attendance as of two hours' duration, with a total attendance of hours.

4. Of having been engaged during a period of not less an six months in acquiring a practical knowledge of the ties, routine and special, of public health administration der the supervision of a Medical Officer of Health, and having received, from such officer or other competent edical Officer during not less than three hours on each of) working days, practical instruction in those duties and so those relating to : (*a*) Maternity and Child Welfare rvice ; (*b*) Health Service for children of school age,) Venereal Diseases Service ; (*d*) Tuberculosis Service ;) Industrial Hygiene ; (*f*) Inspection and Control of Food ; cluding meat and milk.

The above certificate (4) must be obtained from a edical Officer of Health who devotes his whole time public work, or from a Medical Officer of Health a Sanitary Area having a population of not less an 50,000, or in Ireland the Medical Superintendent fficer of Health of a County or County Borough aving a population of not less than 50,000.

Unirersity of Oxford.—An examination, conducted rtly in writing, partly vivâ voce, and in each subject rtly practical, is held in Michaelmas and in Trinity erm in the following subjects :—General Hygiene, eneral Pathology (with special relation to Infectious iseases), the Laws relating to Public Health, Sanitary ngineering, Vital Statistics. The examination is in vo parts, which may be taken together or separately ; rt Part I. must be passed either before or at the same xamination as Part II.

The First Part of the examination will comprise) written papers of three hours each in (i.) Chemistry nd Physics, and (ii.) Pathology and Bacteriology ;) a three hours' practical and vivâ voce examination in hemistry and Physics ; (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

The Second Part of the Examination will consist the following parts :—(*a*) Two written papers, ch of three hours, dealing with General Hygiene ncluding Sanitary Engineering, Vital Statistics, and he Laws relating to Public Health) ; (*b*) a practical nd vivâ voce examination in General Hygiene ; and) a three hours' practical and vivâ voce examination Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce certificates (1) of Laboratory Work in Chemistry, Physics, Meteorology, and Climatology as applied to Hygiene, and (2) of having had Practical Instruction in Bacteriology and Parasitology and the Pathology of the Diseases of Animals transmissible to Man.

Candidates in Part II. will produce the following further certificates : (3) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration ; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration.

All the above degrees are now open to Women Students, and particulars of Scholarships and Prizes may be obtained from the Principals of the various Ladies' Colleges. The names of candidates for the Diploma in Public Health must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford. Applications for any further information should be addressed to the Dean, Department of Medicine, Museum, Oxford.

University of Cambridge.—Two examinations in so much of State medicine as is comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option ; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) Part I. of the examination ; or (2) Part II. of the examination. Candidates must before admission to either part of the examination produce evidence of having satisfied the regulations applicable to Part I. and Part II. The examination for Part I. is in April and for Part II. in October.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University on Hygiene, Chemistry, &c., and on Bacteriology and Parasitology. For Part II. the Medical Officer of Health for Cambridge gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital ; and the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology. There are also courses by special lecturers in Vital Statistics, Tuberculosis Service, Venereal Diseases Service, Industrial Hygiene, Maternity and Child Welfare. These courses are open to non-members of the University.

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England. The courses and examinations are the same as for the Diploma in Public Health (except that the candidates are not examined in English Sanitary Laws).

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.—Candidates for the M.D. Degree may offer State Medicine as a subject in which to graduate. The regulations have been revised and may be obtained on application to the Academic Registrar, University of London, South Kensington.

University of Durham.—The Degree of Bachelor of Hygiene (B.Hy.) and the Diploma in Public Health (D.P.H.).—No candidate is admitted to the final examination for the Degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University whose degrees are registrable on the books of the General Medical Council of the United Kingdom, and no candidate is admitted to the final examination

for the D.P.H. unless he is a registered medical practitioner, of not less than two years' standing. The course of study for the B.Hy. and D.P.H. extends over a period of not less than 12 calendar months, subsequent to the attainment of a qualification registrable by the General Medical Council of the United Kingdom. Candidates for the B.Hy. must attend this course at the University of Durham; candidates for the D.P.H. may attend it at the University of Durham, or at any medical school or institution which is recognised by the University. The examination for the diploma or degree is divided into two parts. A candidate must pass in all the subjects of Part I. before being admitted to examination for Part II. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. The examination for Part I. is practical, written, and oral, and includes the following subjects: Bacteriology and Parasitology (including medical entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. Candidates are not admitted to examination for Part I. until after they have completed the prescribed courses of instruction in the subjects thereof. The examination for Part II. includes Hygiene and Sanitation (comprising sanitary construction), Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination is written and oral, and includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—Dwellings, Factories, Workshops, Schools, &c. Candidates are not admitted to examination for Part II. until after they have completed the prescribed courses of instruction in the subjects thereof. Doctor of Hygiene (D.Hy.): Candidates must be Bachelors of Hygiene of the University of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of Public Health.

Victoria University of Manchester.—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examination will begin about the middle of July and the middle of October in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice. An examination for a Diploma in Bacteriology is held for graduates in science or medicine who have attended prescribed courses for at least one academic year; candidates must present a satisfactory thesis on an approved subject.

University of Birmingham.—Under the revised rules and regulations of the General Medical Council the University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. A Thesis on the Ætiology and Prevention of a Disease of which the candidate has made a special study must be submitted on entry for B.Sc. Part II. The examinations will be held in the months of March and October, and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidate may enter for Parts I. and II. separately or at th same time. The fee for each part of the examinatio is £6 5*s*. Medical Officers of th Navy and Army are admitted to Part II. Examinatio (D.P.H.) on complying with the requirements lai down for attendance upon Courses of Study. Thes Courses need not necessarily be attended in th University of Birmingham.

University of Liverpool.—The University grants Degree in Hygiene (M.H.) and a Diploma (D.P.H. and every facility is afforded for training in Sanitar Science and State Medicine. The curriculum for th Degree extends over a period of two years, the firs of which is devoted to laboratory instruction an practical classes (including those for the Diploma) the second being devoted to advanced study an research. The courses may be taken at any tim and students are allowed to work daily in th laboratories.

University of Leeds.—The University grants Diploma in Public Health, and every facility i afforded for training in Sanitary Science and Stat Medicine. The examination, which is held twice i each year—namely, in June and December—is i two parts, and is written, oral, and practical. Can didates must pass in Part I. before being admitted t Part II. Instruction in Entomology and Meteorolog is given in the first term, and in Sanitary Chemistr and Bacteriology in the second and third term Practical work under arrangement with the Leed City Council. Prospectus can be obtained from th Academic Sub-Dean of the Medical School.

University of Bristol.—Diploma in Public Healt Candidates must be at least 23 years of age, shall b fully registered medical practitioners of not less tha two years' standing as such, and shall have passe the examination prescribed by regulations, which ca be obtained from the Registrar upon application.

University of Wales.—Candidates for the Diplom in Public Health, the curriculum for which extend over a period of not less than twelve calendar month subsequent to the attainment of a registrable qualif cation, must produce evidence of having attende for not less than five months at the Welsh Nationa School of Medicine or at an institution approved b the Court, practical instruction in Bacteriology an Parasitology, Chemistry and Physics, and Meteorolog and Climatology in relation to Public Health. Cand dates must also satisfy the examiners that they hav received instruction approved by the University i the Principles of Public Health and Sanitatio Epidemiology and Vital Statistics, Sanitary La and Administration, and Sanitary Construction an Planning. The candidate must also produce evidenc that he has attended for three months on the clinica practice of a hospital for infectious diseases con taining not less than 100 beds, and has received therei instruction in the methods of administration, and tha he has for a period of not less than six months bee engaged in acquiring a practical knowledge of th duties, routine and special, of a public healt administration under the supervision of a medica officer of health. The examination for the diplom is divided into two parts, Part I. and Part II., each o which extends over not less than two days. A candi date must pass in all the subjects of Part I. befor being admitted to Part II. of the examination. I Part I., and also in Part II., a candidate must pas in all the specified subjects at one time. Part I. of th examination is practical, written and oral, and compris Bacteriology and Parasitology (including Medica Entomology); Chemistry and Physics, and Meteor

y and Climatology in relation to Public Health. ndidates may not be admitted to Part I. of the amination until they have been certified as having rsued the prescribed courses of instruction in the bjects thereof. Part II. of the examination, which is itten and oral, comprises: Hygiene and Sanitation cluding Sanitary Construction); Epidemiology and fectious Diseases; Sanitary Law and Vital Statis-s; Public Health Administration. No candidate n be admitted to Part II. of the examination until er the lapse of not less than two years from the date his obtaining a registrable qualification in Medicine, rgery, and Midwifery, which qualification must be istered before admission to Part II. of the examina-n. An examination in each part will be held nually. The examination in Part I. will be held in ne, that in Part II. in October. Full information m the Registrar of the University, University gistry, Cathays Park, Cardiff, not later than y 15th for the examination in Part I. and not er than Sept. 1st for the examination in Part II.

Iniversity of Edinburgh.—Candidates for the ploma in Public Health must be graduates in medi-e and surgery of the University, or hold corre-nding degrees or registrable medical qualifications ich must be registered before admission to mination. The course is divided into two parts which examinations are held twice yearly, in rch and July for Part I., and in October and rch for Part II. In each part the candidate st pass in all the specified subjects at one examina-n. Candidates are not admitted to Part II. until y have passed Part I., nor until after the lapse of less than two years from the date of obtaining registrable medical qualification. The subjects the examination are: Part I. (written, oral, and ctical), Bacteriology; Medical Entomology and rasitology; Chemistry, Physics, Meteorology, and matology. Part II. (written, oral, and practical), giene, Sanitation, and Sanitary Construction; idemiology and Infectious Diseases; Sanitary Law l Vital Statistics; Public Health Administration. ere is also included practical examinations in fectious Diseases, Food Inspection, and Inspection Premises. The course, which extends over a iod of 12 calendar months, begins in October, and vision is made by the University for instruction in the subjects. Detailed particulars may be obtained m the Dean of the Faculty of Medicine.

Iniversity of Aberdeen.—Every candidate for the ploma in Public Health must be a graduate in dicine of the University of Aberdeen, or of y other University whose medical degrees are ognised as qualifying for registration by the neral Medical Council of the United Kingdom. candidate will be admitted to the Final Part the Examination for the Diploma until after lapse of not less than two years from the date of obtaining a registrable qualification in Medicine, ich qualification shall have been registered before h admission. The whole of the prescribed cur-lum of study must be undertaken after the didate has obtained a registrable qualification in dicine, and shall extend over not less than twelve ndar months. At least one academic term must spent at the University of Aberdeen. Every didate shall produce evidence of having complied h the following requirements in respect of study l training:—1. Practical instruction in the follow-subjects within a laboratory or laboratories roved by the University: (*a*) Bacteriology and rasitology (including Medical Entomology), in tion to diseases of man and diseases of lower mals transmissible to man—at least 180 hours, of ich not less than 150 shall be occupied in practical oratory work; (*b*) Chemistry and Physics, in tion to Public Health—at least 90 hours, of which less than 70 shall be occupied in practical labora-y work; (*c*) Meteorology and Climatology, in tion to Public Health—at least 10 hours; such truction to extend over not less than five months or two academic terms. 2. A course or courses of instruction extending over not less than 80 hours dealing with: (*a*) The Principles of Public Health and Sanitation—30 hours; (*b*) Epidemiology and Vital Statistics—20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services)—20 hours; (*d*) Sanitary Construction and Planning—10 hours; such course or courses to be given at an institution or by a teacher or teachers approved by the University. 3. Practical instruction, clinical and administrative, within a recognised hospital for general infectious diseases; such instruction to extend over three months, and to include 30 daily attendances of not less than two hours in each week. 4. Practical instruction and experience, during not less than six months (including attendance of at least three hours on each of sixty working days) in the duties, routine and special, of public health administration, under the supervision of a medical officer of health, who shall certify that the candidate has received from this officer or other competent medical officer, practical instruction in these duties, and also in those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The medical officers of health recognised for this purpose by the General Medical Council are: (*a*) a medical officer of health who devotes his whole time to public health work; or (*b*) the medical officer of health of a sanitary area having a population of not less than 50,000; or (*c*) in Ireland, the medical superintendent officer of health of a county or county borough having a population of not less than 50,000. The examination for the diploma is divided into two parts, each of which extends over not less than three days.

University of Glasgow.—Degree of B.Sc. in Public Health.—Candidates must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose by the University Court. Candidates must produce evidence (1) that, after they have obtained a registrable Degree in Medicine, a period of not less than two years has elapsed; (2) that, after they have obtained a registrable degree in Medicine, they have, during a period of not less than 21 calendar months, pursued the course of work and instruction prescribed, and have satisfied the examiners in the prescribed examinations. There are two examinations. Part I. includes the following subjects: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health; (iv) Higher Chemistry in relation to Public Health; (v) Physics and Geology. A candidate must pass in the subjects marked (i), (ii), and (iii) of Part I. at one examination. Part II. includes the following subjects: (vi) Hygiene and Sanitation (including Sanitary construction); (vii) Epidemiology and Infectious Diseases; (viii) Sanitary Law and Vital Statistics; (ix) Public Health Administration; (x) Applied Hygiene. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene may be on a selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.).*—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical

qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written and oral, is divided into two parts, Part I. and Part II., each of which extends over not less than two days. No candidate is admitted to either part of the examination until he has completed the prescribed courses of instruction in the subjects of that part. No candidate is admitted to Part II. until he has passed in all the subjects of Part I., nor until after the lapse of not less than two years from the date of his obtaining a registrable medical qualification, nor unless he presents a certificate showing that his name and qualification have been duly registered in the Medical Register. Part I. includes: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health. A candidate must pass in all the subjects at one examination. Part II. includes: (iv) Hygiene and Sanitation (including Sanitary Construction); (v) Epidemiology and Infectious Diseases; (vi) Sanitary Law and Vital Statistics; (vii) Public Health Administration. A candidate must pass in all the subjects at one examination. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like.

University of St. Andrews. — The Diploma in Public Health is open to those who hold a registered medical qualification of the United Kingdom. The examination is in two parts. (1) (*a*) Bacteriology and Parasitology; (*b*) Chemistry and Physics; (*c*) Meteorology and Climatology. (2) Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. Before admission to the first examination the candidate must have held his medical qualification for one year, and before admission to the second examination for two years. Graduates in Medicine of the University of St. Andrews may take part or all of the qualifying classes in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised by the University Court, but holders of other registered medical qualifications must spend at least eight out of the 12 months' curriculum in St. Andrews University. University of Dublin (*Trinity College*).—The Diploma in Public Health is conferred, after examination, under the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least two years before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, five months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have received instruction in the following subjects: the principles of public health and sanitation, epidemiology and vital statistics, sanitary law and administration (including public medical services), sanitary construction and planning; must have studied, practically, outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

*National University of Ireland.**—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health.

* No returns.

University of Belfast.—A Diploma in Public Healt is given by examination. Every candidate mu produce evidence that, after obtaining a registrab qualification, he has during six months receive practical instruction in an approved laboratory which Chemistry, Bacteriology, and the Patholo of the diseases of animals transmissible to man a taught. After obtaining a registrable qualificatio every candidate must produce evidence that he h attended during three months the practice of hospital for infectious diseases at which opportuniti are afforded for the study of methods of administr tion. The examination must have extended over n less than four days, one of which shall have be devoted to practical work in a laboratory, and o to practical examination in, and reporting on, subjec which fall within the special outdoor duties of medical officer of health. The first part of the examin tion will have reference to the general principles Sanitary Science and the second part to State Medici and to the applications of Pathology and Sanita Science. The examination in both parts is he twice a year, in March and June.

Royal College of Physicians of Edinburgh, Roy College of Surgeons of Edinburgh, Royal Faculty Physicians and Surgeons of Glasgow.—All candidat for the Diploma in Public Health must have qualification which has been registered under t Medical Acts. Candidates must have attended n less than four calendar months' practical instructi in Chemistry and Physics (90 hours), Bacteriolo and Parasitology (180 hours), and Meteorology a Climatology (60 hours) in a recognised laboratory laboratories, must have studied outdoor sanitary wo for six months under a medical officer of health other sanitary officer; and must give evidence attendance for three months at the practice of Hospital for Infectious Diseases, at which he h received instruction in the methods of administratic The examination consists of two parts, and candida may enter for both at one period or for either separate The First Part includes (*a*) Laboratory Work (Che istry and Bacteriology), (*b*) Physics and Meteorolog and the Second Examination embraces (*a*) Rep on Premises visited, (*b*) Examination at Fever Hospit (*c*) Examination at Public Abattoir, (*d*) Written a Oral Examinations on Epidemiology and Endemiolo (*e*) Vital Statistics and Sanitary Law, and (*f*) Practi Sanitation. The fee is 12 guineas for both examin tions, or 6 guineas for either of them. A fee 3 guineas is payable by rejected candidates for eitl examination. The examination is held twice year in May in Glasgow, and October in Edinburgh. T published regulations provide detailed synopses of t subjects of examination. *The curriculum and examin tion have been adjusted fully to meet the requirements the regulations of the General Medical Council wh came into force on Jan. 1st, 1924.* Candidates applyi for Regulations should state date of commencem of curriculum. The Registrar for Edinburgh is D. L. Eadie, 49, Lauriston-place, and for Glasg Mr. Walter Hurst, 242, St. Vincent-street.

Royal College of Physicians of Ireland and Ro College of Surgeons in Ireland.—Every candid for the Diploma in Public Health must obse the following rules: 1. A period of not less th two years shall elapse between the attainm by a candidate of a registrable qualification Medicine, Surgery, and Midwifery, and his mission to the Final Examination for a Diplo in Public Health. 2. The curriculum for a Diplo in Public Health shall extend over a period not less than 12 calendar months subsequent the attainment of a registrable qualificati 3. Every candidate shall produce evidence having attended, during a period of not less th five months, at an institution approved by Licensing Body granting the Diploma, practi instruction in—(*a*) Bacteriology and Parasitol (including Medical Entomology), especially in th relation to diseases of man, and to those diseases

lower animals which are transmissible to man; Chemistry and Physics in relation to Public lth; (*c*) Meteorology and Climatology in relation ublic Health. At least 180 hours must be devoted ourse (*a*), of which not less than 150 hours shall occupied in practical Laboratory work. At least ours must be devoted to Course (*b*), of which not than 70 hours shall be occupied in practical oratory work. At least 10 hours must be devoted ourse (*c*). 4. Evidence of having received, during less than 80 hours, at an institution or from hers approved by the Licensing Body granting Diploma, instruction in the following subjects: The Principles of Public Health and Sanitation; Epidemiology and Vital Statistics; (*c*) Sanitary and Administration (including Public Medical vices); (*d*) Sanitary Construction and Planning. vidence that he has attended for three months the clinical practice of a recognised Hospital for ctious Diseases. 6. Evidence that he has, during a od of not less than six months, been engaged in uiring a practical knowledge of the duties, routine special, of Public Health Administration under supervision of a Medical Officer of Health. examination for the Diploma is divided into two ts. The examination for Part I. includes Bacterio- and Parasitology (with Medical Entomology); mistry and Physics, and Meteorology and Clima- gy, in relation to Public Health. The examina- for Part II. includes Hygiene and Sanitation h Sanitary Construction); Epidemiology and ctious Diseases; Sanitary Law and Vital tistics; Public Health Administration. The exa- ation, which is written and oral, includes ctical examinations in Infectious Diseases; Food pection; Inspection of Premises—dwellings, fac- es, workshops, and schools.

DENTAL SURGERY.

EGISTRATION on the Medical Register entitles a ctitioner to practise as a dentist, although he not register as such without degree or licence in tistry; but few dental appointments at general or ial hospitals or dispensaries are available save to se with a special diploma, and until registered the Dentist Register, no dental work under the litional Benefit Scheme of the National Health rance Act can be undertaken.

he Examining Bodies in Dentistry which grant rees and diplomas in the subject are as follows: yal College of Surgeons of England, Royal College Surgeons, Edinburgh, Royal Faculty of Physicians Surgeons of Glasgow, Royal College of Surgeons reland, and the following Universities: Birming- n, Bristol, Durham, Leeds, Liverpool, London, nchester, Sheffield, St. Andrews, Dublin (Trinity lege), Queen's University of Belfast, and the ional University of Ireland. The respective uirements of the various examining bodies in tistry are very similar, being designed to meet requirements of the General Medical Council, the examinations vary in stringency, and each ool has its rules for matriculation and exemp- n, and its scale of fees. The student should apply he secretaries of the various Conjoint Boards or to Deans of the medical faculties or medical schools a syllabus.

EACHING INSTITUTIONS IN DENTISTRY: LONDON.

oyal Dental Hospital of London, School of Dental gery, Leicester-square.—A school of the University London. Women are admitted as students are eligible for all hospital appointments and ool prizes. The school provides the special dental cation required by the Royal College of Surgeons the Licence in Dental Surgery. The general part the curriculum may be taken at any general pital. The hospital is open from 9 A.M. to 5 P.M., re being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25, open to pupils of the Hospital only. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. For full information as to scholarships and prizes, and other matters connected with the course, application should be made to the Dean.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the *National Dental Hospital*, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A prospectus containing full information as to lectures, fees, and prizes may be had on application to the Sub-Dean for Dental Students, who attends at University College Hospital Medical School, University street, W.C.1, on Wednesday mornings from 9.30 to 10.30, and at other times by appointment.

Guy's Hospital Dental School.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for both general and local anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrators, the dental house surgeons, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. There is a separate room for denture patients affording accommodation for 15 chairs and a separate department for children with accommodation for 20 chairs. The Members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by two demonstrators, a house surgeon, and five mechanics.

Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these

two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge.

Twelve house surgeons, 20 assistant house surgeons, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, dresser in the children's department, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and local anæsthetic extraction rooms, and probationary dresser. For particulars as to scholarships and prizes, as well as all information, application should be made to the Dean of the Medical School, Guy's Hospital, London Bridge, S.E. 1.

King's College Hospital.—The Dental School is part of the Medical School of King's College Hospital, and was opened in November, 1923. The Dental Out-patient Department of the Hospital is used for the performance of dental extractions. A large Conservation Room with provision for 40 dental chairs has been equipped. Smaller rooms are used for clinical teaching and administrative requirements, and a specially equipped laboratory for training in the art of dental mechanics. An X ray apparatus has been installed for special use in dental skiagraphy. A museum containing a large number of specimens illustrating oral, buccal, dental, and other diseases is available for teaching purposes. The library, lecture theatre, lecture rooms, common rooms, and the refreshment room are all available for the use of students. Courses of study, including practical work, are provided for the degree of Bachelor of Dental Surgery of the University of London, and for the Diploma in Dental Surgery of the Royal College of Surgeons of England. Special arrangements are made for those students who wish to take a medical degree or qualification in addition to a degree or diploma in Dental Surgery.

The following salaried appointments are open to qualified members of the School: Registrar, Resident House Surgeon, Non-Resident House Surgeon, and Tutor in Dental Mechanics.

Full particulars of the Dental School may be obtained on application to the Dean, or to the Secretary of the Medical School, King's College Hospital, Denmark Hill, London, S.E.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses, in addition to the Theatres, Laboratories, and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Metallurgy and Prosthesis. A systematic course of instruction is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean of the Medical School.

Degree of t University of London and the Licence in Den Surgery of the Royal College of Surgeons of Engla at the London (Royal Free Hospital) School Medicine for Women.

TEACHING INSTITUTIONS OUTSIDE LONDON.

Birmingham Dental Hospital, Great Charles-street Dean: Cyril Howkins, C.B.E., D.S.O., M.R.C L.D.S. The Dental Hospital has accommodation 100 students. The equipment is in accordance w the most modern requirements for the efficient teach and practice of Dental Surgery, including Radiol and Ultra-Violet Ray Therapy and a new departm for Practical Pathology and Bacteriology. operations performed annually average 35,000, incl ing gold and other fillings, crowns, bridges, porcel inlays, and injections for block and infiltrat anæsthesia. The orthodontic department is one the foremost in the country. The Prosthetic a Mechanical Department is large and well lighted a under a highly skilled instructor who is alw present. Application for information as to fees a scholarships must be sent to the Dean of the Med Faculty, Birmingham University, or the Dean of Dental Hospital, Birmingham.

Leeds University School of Dentistry.—The Schoo Dentistry is adequately equipped to provide for complete training of the dental student. It fo a part of the Leeds School of Medicine whilst instruction in clinical and mechanical dentistry carried out in the Dental Hospital. The Schoo now in occupation of a spacious new build especially designed to the requirements of mod dental teaching. The School is also the de department of the General Infirmary, and its cl association with the work of that institution ens an adequate supply of clinical material, and ena a fuller insight into the position dental surg holds in relation to general medicine and surg especially with regard to the major diseases injuries of the head and neck. The courses of st are mainly designed to meet the requirements of B.Ch.D. and L.D.S. Leeds, but every opportunity afforded to students preparing for the degrees diplomas of other licensing bodies. Full-time dem strators give the instruction in clinical dental surg prosthetic dentistry, and mechanics, which is car out under the supervision and direction of membe the Honorary Staff, two of whom are in attenda each day. Special facilities are provided for instruct in Orthodontia, Dental Radiography, Local General Anæsthetics. Prizes are offered for comp tion to pupils and students in their respective y of study. Communications should be addressed the Warden, School of Dentistry, Leeds, from wh a prospectus may be obtained.

Dental Hospital of Manchester.—This hospital i association for teaching purposes with the Univer of Manchester and the Royal Infirmary, and is the centre of a very large population. Courses study are provided to meet the requirements of various examining bodies, including those of University of Manchester for the qualifications L.D and B.D.S., and the L.D.S. of the Royal Colleg Surgeons of England. Clinical instruction is gi in Dental Prosthetics, Operative Dentistry, Diagn and Extraction, Orthodontics, Dental Surgery, Ra graphy, and Anæsthetics by specially appoin Clinical Teachers.

All the courses of instruction are open to wo students. Copies of the Prospectus will be forwar on application to Mr. J. Hilditch Mathews, Dean

Newcastle-upon-Tyne Dental Hospital and Schoo This hospital is centrally situated (within five min of the various colleges, infirmary, and railway statio

rooms are well lighted and thoroughly equipped carrying on the work. Dental surgeons and an esthetist attend each morning. A tutorial dental geon and a prosthetic tutor are also in attendance. dals and Certificates of Merit are granted to dents showing certain standards of proficiency the various classes at the Dental School. The spectus of the Dental Hospital and School, con- ning full information, may be obtained from . James Coltman, 13, Ellison-place, Newcastle- on-Tyne, Dean.

Devon and Exeter Dental Hospital, 24, Southernhay st, Exeter.—The hospital is open on Mondays, esdays, Wednesdays, Thursdays, Fridays, and urdays, and patients are admitted between the rs of 9.30 and 11 A.M. Students attend the ctice of the hospital under the control of the dical officers.

Scottish Teaching Institutions.

The Incorporated Edinburgh Dental Hospital and ool.—The Edinburgh Dental Hospital and School located in spacious and well-equipped buildings 30, 31, and 32, Chambers-street, and offers special vantages to dental students. A large and important ension of the existing buildings has now been ned. The General Courses required for the ntal Diploma may be taken in the Medical ool of the Royal Colleges of Physicians and geons or in the University schools. The general pital attendance and clinical instruction are taken the Royal Infirmary. The University, Medical ools, and Royal Infirmary are within three minutes' lk of the Dental Hospital. The special courses are en in the hospital. The Dental Hospital practice, ending over two years, affords a student ample portunity for a full acquaintance with every branch dentistry. The hospital admits a limited number indentured pupils. They receive their instruction Mechanical Dentistry concurrently with the general l special courses. A premium of 60 guineas is yable with each such pupil. The practice and tures of the hospital are recognised by, and qualify , all the Licensing Boards. Those students who ire to take a Medical and Surgical Diploma in lition to the L.D.S. have in this school admirable ilities for so doing. The triple qualification of the yal College of Physicians and Surgeons of Edinburgh l the Royal Faculty of Physicians and Surgeons of sgow is recommended. The Higher Dental ploma (H.D.D.) of the Royal College of Surgeons ords an opportunity of obtaining a higher qualifica- n subsequent to registration. The Prospectus, with l information, may be obtained by application to Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital, 158, Renfrew- eet and 15, Dalhousie-street, Glasgow.—The School pen to Men and Women Students, and Lectures given on Dental Surgery, Operative Dental rgery, Orthodontia, Dental Anatomy and Physio- y, Dental Histology, Dental Mechanics, Crown and dge work, Dental Metallurgy, Dental Bacteriology, diology, Anæsthetics, and Dental Materia Medica. ctures on general subjects required for Dentistry y be taken at the University or at one of the extra- ral schools where special provision is made for ntal Students. A new mechanical laboratory with ch accommodation for 60 pupils and fully equipped h the most modern appliances for teaching practical tal mechanics has recently been added. Full ormation may be had on application to the Dean.

Glasgow Royal Infirmary (Dental Department).—e following course in the curriculum can be taken St. Mungo's College: Anatomy, six months; actical Anatomy, nine months; Physiology, six nths; Chemistry, six months; Practical Chemistry, ee months; Surgery, six months; Medicine, six nths; Materia Medica, three months; Dental rgery, six months, and attendance for two years the dental department of the hospital. Clinical Medicine (three months) and Clinical Surgery (six months) are taken at the Royal Infirmary.

Ireland.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their Second Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

PRISON MEDICAL SERVICE.

Candidates for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from the seniors of this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £600, making the pay at present with bonus £485 8*s.* to £776 7*s.*; Medical Officer, Class I., £650, rising by annual increments of £25 to £800, plus bonus, making the pay £837 5*s.* to £995 11*s.* Unfurnished quarters are provided or an allowance in lieu is made. Study-leave is granted annually to two of the whole-time Medical Officers. There are 12 full-time medical officers of Class I. and 15 Class II., and 23 part-time medical officers. The number of vacancies is never large and promotion is slow.

The Elizabeth Garrett Anderson Hospital.—Application for a Charter of Incorporation has been made by the Marchioness of Dufferin and Ava and others on behalf of the Elizabeth Garrett Anderson Hospital.

International Medical Post-graduate Courses in Berlin.—In connexion with the Medical Faculty of Berlin post-graduate courses are held by the Lecturers' Association for Medical Continuation Courses and the Kaiserin Friedrich-Haus. The regular courses last from two to four weeks; other courses for those wishing to act as resident assistants in clinics, hospitals, and laboratories, lasting two to three months and longer, are arranged under systematic supervision. Courses will also be held next month as follows: Oct. 1st to 13th, General Survey of Medical Progress with Special Reference to Pulmonary Diseases; Oct. 8th to 20th, Nose, Throat, and Ear Course for Specialists; Oct. 15th to 27th, Pediatry. There will also be a course on New Methods of Diagnosis and Therapy, with practical clinical studies and exercises in the City Hospital, Friedrichshain, and its laboratories, as well as single courses in special fields of medical science, including practical work. The courses are held in German, but some of the professors speak English, French, and Spanish, Further information and details as to lodgings and so forth can be obtained from the Kaiserin Friedrich-Haus, Luisenplatz 2–4, Berlin, N.W. 6.

PUBLIC AUTHORITIES AND RESEARCH.*

By JAMES M. BEATTIE, M.D. Edin.,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LIVERPOOL.

At present there are a few public authorities which encourage research to a limited extent, but the great bulk of them do practically nothing, and research is largely financed by private individuals, or by universities and colleges which can ill afford the money. I do not forget the national effort in our Medical Research Council and what is done under the direction of the Ministry of Health and the Ministry of Agriculture. But the work of these ministries is restricted and greatly hindered by want of funds. Very often, before any substantial results are obtained, it is interrupted because the money voted is exhausted. The Medical Research Council also is hampered by financial considerations, and one sometimes wonders whether those under whose direction the work is done have really an absolutely free hand. Large organisations of this kind, whether supported by Government or by private associations with large committees, have of necessity to produce reports at stated intervals, and these reports must contain results of work done. Not uncommonly that work is unfinished and not thoroughly controlled; the investigators fully realise this, but the committee has to be satisfied, and the subscribers expect results for the money they have given.

Danger of Directing Research.

I think these large organisations have other decided disadvantages. It is a necessity that there should be someone directing the different branches of the research carried on. He may be a very able man, and he usually is. He forms his plan of investigation, and his workers having that plan before them pursue lines which lead to the central point in that plan. There is the one brain which dominates and the investigator must not follow side-tracks. Of all new information which comes to him during the course of his investigation, only that information can be accepted which seems to help him along the special track which has been chosen, and if the track is wrong then a new track has to be found, and months, and even years, of research have merely led to an impassable wall.

I do not underrate the value of such work—barren though the final result may be—but what I do deprecate is that by the establishment of central institutes there are only a limited number of tracks blazed. There are numbers of men who, given an opportunity, would see other roads, so that instead of one man planning a special line of attack there would be a dozen men possibly planning a dozen lines, with an increased probability of success. For this reason, but not for this alone, I would urge that research centres should be as widespread as possible.

Disadvantages of Research Institutes.

The research institute is generally divorced from the hospital, and it is almost inevitable that the clinical side of disease in the human subject should be ignored in favour of animal experiment. If progress is to be made it is, to my mind, essential that the hospital and the research department should be closely associated, and the research worker should, by preference, be a man with experience as a clinician. But in practice we find our research institutes staffed by young men—very often brilliant young men—who have just qualified and whose real experience of disease is extremely limited. Is it to be wondered at that much of what they do has little or no bearing on the problems of the everyday practice, and that the laboratory worker is becoming more and more a pure scientist, separated entirely from the clinician? Let me say, in passing, that the laboratory worker is not altogether to blame, for many clinicians show no desire to a the pathologist or to give him any facilities for keepi in touch with the sick man. The research institu I believe, helps in this separation; certainly the would be less tendency towards it if the resear laboratory were intimately associated with a hospit as most of our university laboratories are.

Again, it may be asked, is the money expended the best advantage? I am not here concerned wi places like the Rockefeller Institute, which have hospital attached and where there is neither financ restriction nor an obligation on the research work to show cause for his existence, but I refer rather the ordinary research institute with its elabora buildings and equipment. The administrative expen are usually very heavy. Much of this expense co be avoided—or, at any rate, the money be m advantageously spent—if the workers were dist buted over the various laboratories now in existen and these research centres spread widely over t country.

Organisation versus Initiative.

We all rejoice in the present great national app for cancer research, but how will the money be use A great research worker said to me a few weeks ag "This appeal has killed cancer research."—"Why I asked. "Because we are out for something bi he answered, "something that will appeal to t people. The man who has been working quietly a steadily in his own laboratory—hampered, it is tr by want of funds—is likely to be absorbed into institute; his initiative will be crushed because he l to work along a plan made by a director, and mon which could be used to finance these individual work will go to the erection of buildings—e.g., can hospitals—and to administrative expenses." T may be a pessimistic view, but it is one which dema our earnest consideration. I am still a believer the individual worker, financed properly—one w uses his own brains, thinks out his own problems, a gets himself in touch with his fellow workers in t same field, and discusses with them his ideas. Tea work has been tried, but I venture the opinion th most men who have had experience of it are looki forward to the funeral rather than to the festival.

A contemporary writer speaks of the loss efficiency consequent on "subjecting policy to t constant censorship of uninformed critics" as one the evils of democratic government. This censorsl and this criticism in research is one of the great evils of the committee system of directing it.

We have seen some evidence of this in the rec reports on cancer research. For instance, the very f that public discussion of the lead treatment of can has been necessary at this stage is because the wh research on cancer has come under the auspices o Committee which must publish its results in order stimulate the public to raise more money. I say th such public discussion has done a great deal of ha to the progress of the research.

A Better Way.

If the local authorities will agree to give facilit in their various hospitals and institutions and t universities and colleges will place their laborato and their trained staff at the disposal of these worke then the thing, administratively, is accomplish The administrative expenses would be small, as t laboratories at present in existence at the universit could be used and the head of the university depa ment would supervise the work. Thus, there wo be no expenses for building, and very little apparatus and materials, and the supervising he would, I have little doubt, in most cases, if not in accept the responsibility without extra payment. T main payments would be to the research worke and these should be paid by the local authorit These research workers are, in my opinion, as muc necessity in the hospitals of the local authorities the resident medical officers, but they must be n who have been trained, and they should have,

* Abridged from a presidential address delivered before the Section of Bacteriology, Pathology, and Biochemistry of the Royal Institute of Public Health at Dublin on August 15th.

st, an equal status, financial and otherwise, with senior resident medical officers. They must be sely in touch with the clinical work of the hospital t should have all the advantages of the senior lical officers, with whom they must be in constant aboration.

Let me here say that I do not mean by research ordinary routine examinations which so often stitute the work of the hospital pathologist, nor I mean the ordinary class of work—often designated earch—which is so often produced by the man whose object is to get a higher degree. I mean a real estigation which has for its object the solution of a blem which will throw some light on the cause or atment of disease.

Collaboration of Universities.

Let me outline briefly what I consider should be ne. In the first instance, that local authorities in neighbourhood of a university town should appoint least one qualified research assistant who would e free access to their hospitals and have at the ne time the facilities of the university laboratories, t that the head of these departments should act as isor to the research worker. Laboratory assistance uld be necessary, as the research worker should not required to do a lot of mechanical work which could quite efficiently done by a partially trained man. ould put the maximum annual cost for each research ker at £1500 to cover salary, assistance, and terial. With the appointment of a number of such kers the problems of disease would thus be attacked ng different aspects by a series of workers, all ficiently remunerated to go on for several years, l advised by men of different ideas and different s of thought. They would have facilities of the t, and I am confident that in a very short time the enditure of money would be fully justified. My tention is that with available funds it is far better endow the individual effort than to endow an titute which has certain disadvantages.

The history of medicine goes to show that the atest discoveries and the greatest advances have n made by workers who have worked along inde- dent lines, and who have not been under the trol of special research and other committees, ays on the outlook for reports and publications. identally, I would add that I think it would be a d thing if the scientific medical journals could be pressed for a few years, so that much of the ligested literature of to-day might find its way the waste-paper basket before, and not after, blication.

Research in our universities has been badly anised, hampered on all sides by want of funds t by the lack of hospital facilities. If the money nt on the bricks and mortar, on the equipment, and the maintenance had been spent on university oratories already built and already fairly well ipped, then it would have been more abundant t probably more valuable. Everyone must recog- e that in a University the heads of departments are y with teaching and administration, and research st take a second place, but universities should be ficiently financed to be able adequately to staff ir department so as to relieve the man with the cial capacity for research from much of the routine ministrative and teaching work of the department. ould not free him altogether from teaching, because hink the divorce of teaching and research is remely bad, particularly for the teacher, and in a er degree for the research worker. The University, vever, should be able to relieve the research man m much routine work by giving him satisfactory istants, and at the same time to encourage the it of research among its younger teachers.

An Appeal to Local Authorities.

t may be asked whether this is legitimate work for local authorities. To me it appeals as essentially ir work. Research deals not only with the discovery the cause of the diseases, but with the means of protection against them; the funds for this must come mainly from the national purse and from local authorities. I am not dealing to-day with research under Government control, but would merely say in passing that it is not creditable to our country the way research, in all its branches, is starved. My appeal to-day is to the enlightened local authorities, that they should devote a certain amount of money to systematic research in the laboratories established in their neighbourhood just as they devote money to the treatment of disease. What a stimulus would be given to research if our local authorities were to give even one-tenth of the money they are now spending on administration to existing research laboratories.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 11TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 111 (last week, 126); scarlet fever, 1334; diphtheria, 787; enteric fever, 222; pneumonia, 499; puerperal fever, 58; puerperal pyrexia, 90; cerebro-spinal fever, 12; acute poliomyelitis, 10; acute polio-encephalitis, 1; encephalitis lethargica, 14; continued fever, 1; dysentery, 4; ophthalmia neonatorum, 128. No case of cholera, plague, or typhus fever was notified during the week.

The following counties each notified three or more cases of enteric fever:—London, 69; Bucks, 3; Devon, 5; Essex, 9; Hertford, 3; Kent, 6; Lancaster, 13; Middlesex, 9; Northumberland, 3; Nottingham, 9; Southampton, 3; Surrey, 45; Warwick, 7; Wilts, 4; Yorks, West Riding, 6. The total of 222 includes 147 cases of paratyphoid fever, of which 57 were notified in London and 35 in Surrey.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on August 14th–15th was as follows:—Small-pox, 11 under treatment; scarlet fever, 1614; diphtheria, 1618; enteric fever, 97; measles, 226; whooping-cough, 207; puerperal fever, 12 (plus 9 babies); encephalitis lethargica, 71; poliomyelitis, 12; "other diseases," 15. At St. Margaret's Hospital there were 18 babies with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 5 (1) from enteric fever, 11 (1) from measles, 6 (1) from scarlet fever, 22 (2) from whooping-cough, 22 (5) from diphtheria, 60 (19) from diarrhœa and enteritis under two years, and 15 (3) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London were reported from Liverpool, Salford, Preston, and Sheffield. Of the 20 fatal cases of whooping-cough outside London 3 were reported from Birmingham and 2 each from Liverpool, Manchester, and Newcastle-on-Tyne. Glasgow reported 7 in the same week. Belfast reported 5 fatal cases of measles. The youthful deaths from diarrhœa show scarcely any increase.

The number of stillbirths registered during the week was 254 in the great towns (corresponding to a rate of 42 per thousand births), including 45 in London.

THE LATE COLONEL J. ARNOTT.—The death occurred on August 18th at Kirtlebridge, Dumfriesshire, of Lieut.-Colonel James Arnott, formerly of the Indian Medical Service. The son of Dr. John Arnott, he was born in India in 1845, and went back to the East soon after qualifying in medicine in the University of Glasgow in 1866. He served throughout the Abyssinian Campaign of 1866–68, and was in Afghanistan in 1879 and the two following years, seeing service at Kandahar and being twice mentioned in despatches. He retired from the Indian Medical Service in 1898 after 31 years of medical work, during which he occupied the chairs of pathology and midwifery at the Grant Medical College, Bombay, and held appointments as honorary obstetric physician to the Sir J. Sejabhoy Hospital, and as physician in charge of the St. George's Hospital in the same city. After his retirement Colonel Arnott was a member of the board of the Simpson Memorial Hospital and the Victoria Hospital for Consumption at Edinburgh, and was for many years adviser to the Colonial Office for Scotland.

Medical News.

THE IRISH DENTISTS ACT.—The Dentists Act, which has received the signature of the Governor-General of the Irish Free State, imposes certain duties on the Medical Registration Council. In the first place, it will be the duty of the Council, on request by the Minister, to nominate three members of the Dental Board. These will be the first members of the Board to be appointed, and it will be their duty, together with the member nominated by the Executive Council, to proceed with the election of the remaining members. Further, after the establishment of the Register, the Medical Council will have the duty of satisfying itself that the standard of theoretical and practical knowledge required at the qualifying examinations in dentistry is such as to guarantee the possession of knowledge requisite for the efficient practice of dentistry or dental surgery. The Medical Council is, therefore, the supervising authority in regard to education, but all disciplinary powers are given to the Dental Board. In this respect the Irish Act differs from the law in force in Great Britain. In the form in which the Act passed, there is no interference with the privilege of registered medical practitioners to practise dentistry or dental surgery.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, August 27th, a two weeks' course will begin at the Queen Mary's Hospital, Stratford. This is an all-day course, and instruction will be given in medicine, surgery, and the specialties. From Sept. 11th to Oct. 5th, on Tuesdays and Saturdays at 11 A.M., there will be lecture-demonstrations on Psychological Medicine at the Bethlem Royal Hospital. From Sept. 17th to 29th four courses have been arranged. The Queen's Hospital, Hackney-road, will give a course on Diseases of Children occupying the whole of each day. Lecture-demonstrations in ophthalmology will be given during the afternoon by the staff of the Royal Eye Hospital; an all-day course in orthopædics will be held at the Royal National Orthopædic Hospital; and the Westminster Hospital will give a course, also intensive, in medicine, surgery, and the specialties. From Sept. 26th to Oct. 17th a series of lecture-demonstrations in electrotherapy will be given at the Royal Free Hospital. Copies of all syllabuses and information about the General Course at the affiliated hospitals may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

THE LATE MR. W. M. OAKDEN.—The death occurred on August 12th of William Marshall Oakden, B.Chir. Camb., F.R.C.S. Eng., medical superintendent of St. Luke's Hospital, Lowestoft. Mr. Oakden, who was in his forty-second year, was educated at Peterhouse, Cambridge, entering St. Thomas's Hospital with an entrance scholarship and taking the Bristowe medal. Qualifying in 1911 he served as house surgeon, casualty officer, and medical officer in the infectious wards of his own hospital. During the war he went out with the Salonika expeditionary force, and acted as temporary assistant surgeon at St. George's Hospital. After experience as senior assistant medical officer at Queen Mary's Hospital, Carshalton, he was put in charge of the large convalescent hospital at Lowestoft, where the Metropolitan Asylums Board deals with all its cases of adult surgical tuberculosis.

Vacancies.

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.
Barry Accident and Surgical Hospital.—H.S. At rate of £200.
Bath, Royal United Hospital.—H.P., H.S., and Asst. H.S. At rate of £120 and £100 respectively.
Bedford County Hospital.—H.S., also Asst. H.S. At rate of £175 and £130 respectively.
Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200.
Bradford, Children's Hospital.—H.S. £120.
Bristol General Hospital.—H.P.'s, H.S.'s, &c. All at rate of £100.
Bristol Royal Infirmary.—H.P.'s, H.S.'s. Also Dental H.S. Each at rate of £80.
Cairo, Egyptian Government Public Health Dept.—Director of Endemic Diseases Section. L.E. 900 to 1140.
Cairo, Egyptian University.—Faculty of Medicine: Professor of Forensic Medicine. L.E. 1500. Also Prof. of Clin. Surg., &c.
Calcutta School of Tropical Medicine and Hygiene.—Professor of Tropical Medicine.
Carlisle, Cumberland Infirmary.—H.S. At rate of £175. H.P. At rate of £155. Also H.S. to Special Depts. At rate of £150.
Carmarthen, Joint Counties Mental Hospital.—Jun. Asst. M.O. £300.
Chester Royal Infirmary.—H.P. £120.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each rate of £110. Also Surgeon to Out-patients.
Hayward's Heath, King Edward VII. Memorial (Eliot) Hospi Hon. Surg.
Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—H At rate of £110.
Hospital for Women, Soho-square, W.—Res. M.O. At rate £100.
Hull, City and County of Kingston-upon-Hull.—Asst. M.O £600.
Kingston-on-Thames, Surrey County Sanatorium, Milford, n Godalming.—Sen. Asst. Res. M.O. £500.
Leicester Royal Infirmary.—Res. M.O.'s. Each at rate of £1
Lincoln County Hospital.—Jun. H.S. At rate of £150.
Liverpool, David Lewis Northern Hospital.—Surg. Reg. Asst. Pathologist, Surg. Reg., Tutor and Asst. Patholog Each £145. Also Med. Reg. and Tutor. £120.
Lowestoft, St. Luke's Hospital.—Med. Supt. £800.
Manchester, Monsall Hospital for Infectious Diseases.—Sec Asst. M.O. Also Jun. M.O. At rate of £375 and £ respectively.
Manchester, Park Hospital, Davyhulme.—Three R.M.O.'s. at rate of £150 and two at rate of £120.
Manchester, Royal Children's Hospital, Gartside-street.—A M.O. At rate of £150.
Manchester, Royal Children's Hospital, Pendlebury.—Res. Su Officer. At rate of £125.
Metropolitan Ear, Nose and Throat Hospital, Fitzroy-square, W H.S. £150.
National Hospital for Diseases of the Heart, Westmoreland-str W.—Res. M.O. At rate of £150.
Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. H At rate of £100. Also Res. Sen. H.S. and Res. P. E at rate of £95.
Newport, Mon., Cefn Mably Hospital, Michaelstone-y-vedw Asst. Res. M.O. £200. Also Third Asst. Res. M.O. South Wales Sanatorium, Talgarth, near Brecon. £200
Nottingham City Mental Hospital.—Jun. Asst. M.O. £350.
Plymouth, South Devon and East Cornwall Hospital.—H.S. rate of £50.
Prince of Wales's General Hospital, Tottenham, N.—F Anæsthetist. At rate of £120.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W Asst. Res. M.O. At rate of £80.
Rochester, St. Bartholomew's Hospital. H.P. At rate of £17
Royal Air Force Medical Service.—Commissions.
St. George's Hospital Medical School, S.W.—Pathologist Lecturer in Pathology. £575.
St. Mary Abbot's Hospital, Kensington.—Part-time Patholog &c. £650.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Gard W.C.—H.S. At rate of £75.
Salford Municipal Maternity Home and Babies' Hospital, Seedl terrace, Pendleton.—Asst. Maternity and Child Welf M.O. £600.
Samaritan Free Hospital for Women, Marylebone-road, N.W H.S. At rate of £100.
Truro, Royal Cornwall Infirmary.—H.S. £170.
University College Hospital Medical School.—Radcliffe Croc Travelling Scholarship in Dermatology. £280.
University of London, S. Kensington, S.W.—William Ju Mickle Fellowship. £200.
Wandsworth Borough Council.—Locum Tenens, Asst. M.O. &c. £10 10*s.* weekly.
Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £1
West London Hospital, Hammersmith-road, W.—H.P. and t H.S.'s. Each at rate of £100.
Western Australia Lunacy Dept.—Jun. Asst. Res. M.O. £456
Weston-super-Mare Hospital.—Res. M.O. £130.
Wolverhampton and Staffordshire Hospital.—H.S. At rate £150.

The Chief Inspector of Factories announces the follow vacant appointments for Certifying Factory Surgeons Hawes (Yorks, North Riding), Youlgreave (Derbyshi Southport (Lancashire), Torpoint (Cornwall), and Ol (Bucks).

Births, Marriages, and Death

BIRTHS.

BYRD.—On August 19th, Dr. Elizabeth C. Byrd (née Pow the wife of Dr. John D. Byrd, St. Aubyn, Cecil-aven Ashton-on-Mersey, of a son.

GODDARD.—On August 15th, at Lincoln House, Hemel Hem stead, to Gladys, wife of Dr. T. R. Goddard—a son.

RAINER.—On August 17th, at "Shirlands," Herne Hill, S.E. to Kathleen, wife of Dr. Charles Farrell Rainer—a daugh

MARRIAGES.

JARMAN—CUMMING.—On August 15th, at St. Maryleb Parish Church, W., Mr. Ronald Jarman, L.R.C.P. Lo M.R.C.S. Eng., and Mary Putnam, only daughter of late Mr. James W. Cumming, of Huddersfield, and Cumming, of Haslemere, Surrey.

DEATHS.

SYME.—On August 14th, suddenly, William Smith Syme, Se M.D., F.R.F.P. & S. Glasg., F.R.S.E., of 11, Lynedo crescent, Glasgow.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notice Births, Marriages, and Deaths.

Ingleby Lectures

ON

SOME RECENT ADVANCES IN OUR KNOWLEDGE OF

RICKETS AND ALLIED DISEASES.

Delivered at the University of Birmingham

BY LEONARD G. PARSONS, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE CHILDREN'S AND GENERAL HOSPITALS, BIRMINGHAM.

LECTURE I.*

THE renaissance of medicine, or perhaps it were better to say the birth of physiology, occurred exactly 300 years ago, when the immortal William Harvey published his treatise "Exercitatio Anatomica de Motu Cordis et Sanguinis." It is interesting to speculate on the connexion between this event and the recognition of the disease which forms the subject on which I have chosen to speak. There is no doubt that Harvey's discovery profoundly impressed the scientific world of his time; indeed, his work was universally accepted, and "inculcated as a canon in most of the medical schools in Europe" during his own time. I think that there can be no question that his discovery stimulated many of the doctors of his time to closer observation and led to the recognition of rickets. Although it seems certain that rickets existed at least 200 years before Harvey's day, yet it only appears for the first time in the list of diseases of the London yearly bills of mortality in the year 1634. During the early seventeenth century these bills seem only to have been printed in years of extraordinary mortality. The earliest known copies belong to the year 1625, and there are bills extant for 1629, 1630, 1631, 1632, 1633, 1634, &c., but it is only in the year 1634 that rickets occurs as one of the causes of death. It is probable, however, that Harvey's work had an even more important influence on the knowledge of rickets, since in the year "De Motu Cordis" was published, Francis Glisson was Surgeon in Greek, and in the following year Dean of Caiusville and Caius College, Harvey's own College. It surely must be something more than a mere coincidence that he should then turn his attention to Medicine, proceeding to the degree of doctor of Medicine in the year 1634. Glisson later became one of the members of a small society which met weekly in London for the purpose of promoting inquiries into natural and experimental philosophy, and which after the Reformation developed into the Royal Society. Seven members of this Society, all Fellows of the Royal College of Physicians, "communicated to each other their observations concerning this new disease. From these it was thought proper to make extracts and compose an express treatise on the subject, the care of which was unanimously delegated to Drs. Glisson, Bates, and Regemorter. The plan at first agreed on was that each should take a separate part of the work and complete it. But on Dr. Glisson finishing his, which contained an investigation of the cause of the disease, to the satisfaction of the other two, but with many opinions peculiar to himself, they changed their design and committed to him the planning of the whole work that all its parts might be congruous and dependent on each other." This book, which it will be remembered bore the title "De Rachitide seu morbo Puerili qui vulgo the Rickets dicitur," was a masterly treatise on what he considered to be an entirely new disease which had arisen some 30 years previously in Somersetshire and in his native county of Dorset. The impression created by this work was shown by the fact that rickets has ever since been known in Germany as the English disease.

Although Glisson attributed rickets to disturbed nutrition by arterial blood and believed that the bone changes were due to excessive vascularity, yet it is true to say that according to his conception rickets was a disease of the bony skeleton. He suggested the title rachitis for two reasons, partly because of its likeness to the word "rickets"—the name applied to the disease by the common people—and the other because the vertebral column was so frequently affected in this disease, ραχις being the Greek word for spine. Rickets, on the other hand, is probably derived from the Anglo-Saxon word wrickken (to twist), and was applied to the disease because of the deformities which characterised severe cases. This word has passed into common usage in our language; thus we speak of a rickety chair or table, a phrase which calls up in our minds the picture of a piece of furniture which can well be compared with that of a child suffering from severe rickets whose twisted limbs are ill-adapted to support its weight. Although it is true that the characteristic changes are to be found in the skeletal system, and particularly in that part of the skeleton which is growing rapidly, the view that rickets is a disease of bone is quite wrong. This idea, however, dominated the study of rickets for over 250 years, and it is only fitting that, as the birth of our knowledge of rickets can be claimed for an Englishman, its renaissance and the origin of the present conception of rickets should be shared equally by a Scotsman, Leonard Findlay, and an Englishman, Gowland Hopkins. The modern view of rickets, evolved during the last 15 to 20 years, is that the disease is a general nutritional or metabolic disorder which affects every system of the body, the early symptoms bearing no direct reference to the skeleton. Thus, rickets may show itself as a respiratory disorder in recurring attacks of bronchitis; as a gastro-intestinal affection in recurring diarrhœa; as a nervous disorder in tetany, convulsions, &c.; as a muscular disease in severe hypotonia; but eventually characteristic bone changes always occur. The development and proof of this theory has been in a large degree the work of numerous British and American investigators, and furnishes a most striking example of the interdependence of laboratory research and clinical medicine.

In order to understand how recent researches have added to our knowledge of the very complex problems of the ætiology and cure of rickets, it is necessary to have some knowledge of the radiographic appearances, the chemical processes involved in the deposition of bone, and the histological characters of normal and rachitic bone.

HISTOLOGY.

A longitudinal section of a long bone of an infant shows a clean cut end (epiphyseal line) to the shaft (diaphysis), and a disc of whitish cartilage (epiphyseal cartilage) between this and the bony epiphysis in those instances in which ossification of the epiphysis has occurred. In a rachitic bone quite a different picture is obtained. The width of the epiphyseal disc of cartilage is considerably increased. There is no epiphyseal line, but its place is taken by an irregular frayed end to the diaphysis. This frayed end, which is more vascular than normal, is usually scooped out and expanded laterally, the result of pressure, thus producing the clinical sign of enlargement of the epiphysis. To this altered extremity of the diaphysis the term metaphysis is applied.

Microscopical examination of the growing end of a normal bone reveals in passing from the epiphyseal cartilage to the diaphysis, first, ordinary hyaline cartilage followed by the zone of cartilage proliferation in which the cartilage cells become increased in number and then arranged in columns of 6 to 15 cells. The cells eventually become larger, and the number in each space increased. The cell columns are separated from each other by columns of hyaline matrix. This area is followed by the zone of provisional calcification in which lime salts are

* Lecture II. will appear in a coming issue of THE LANCET.

deposited in the columns of matrix. As a result the columns become rigid and thus direct the budding capillaries from the marrow up against the cartilage cells, which are either destroyed by erosion or become lost in the medullary spaces. The columns themselves are then partly destroyed and partly act as centres round which osteoblasts arrange themselves and form bone which at first contains no calcium and is known as osteoid. In health this osteoid layer is only a narrow area in which calcium is soon deposited and true bone formed.

In rickets this orderly arrangement is completely lost. The zone of cartilage proliferation is increased vertically and laterally, the columnar arrangement being at first manifest, but the cells in the column are more numerous and soon this design is lost and the cells appear as masses in a hyaline matrix. The zone of provisional calcification is absent, with the result that the marrow vessels grow in all directions. The osteoid layer is greatly thickened and forms the rachitic metaphysis; in it are islands of cartilage cells, wide spaces containing marrow, and in its deeper parts irregular depositions of calcium forming true bone and producing the characteristic dentate frayed appearance of the end of the metaphysis.

When healing takes place, the first thing to occur is the deposit of calcium in the cartilage where the zone of provisional calcification should have been. This at first is a thin irregular line, but as healing advances it thickens, depositions of calcium occur in the osteoid tissue, and the cartilage in the metaphysis gradually disappears. Osteoid tissue is also present under the periosteum in larger amounts than normally, producing irregular masses, buttressing, and the elimination of the sharp angles, borders and prominences of the long bones, and giving rise in the membrane bones of the skull to bossing.

The typical microscopical findings in rickets are: (1) the presence of large amounts of osteoid tissue; and (2) the substitution of disorder for order.

Radiographic Manifestations.

These are best studied in the lower end of the radius. Except in very slight cases the bone trabeculæ are more coarse and blurred than normal. This coarsening increases as the disease advances and becomes very marked in severe cases. The appearance of the metaphysis varies with the degree of activity of the child, and, therefore, with the severity of the disease. In those children who are not too ill to be fairly active the end of the diaphysis is scooped out and expanded laterally, the so-called "champagne-glass" appearance. The distance between the epiphysis and the diaphysis is increased, and in place of the sharp epiphyseal line there is an irregular frayed margin. The frayed-out ends of bone gradually fade away towards the epiphyseal disc of cartilage until no bone shadow is seen. This is the characteristic appearance of the rachitic metaphysis in what has been called by Wimberger the active form of florid rickets. The appearance, however, is not seen in all the long bones even in this active form; for instance, it is never seen at the lower end of the humerus. If the disease is so severe that the child is unable to crawl or walk, the passive type of florid rickets is found. In this variety the distance between the epiphysis and diaphysis is still greater, but the transition from bone to cartilage is much more abrupt than in the active form of florid rickets. Although the end of the diaphysis is not sharply defined, yet the irregular fraying is not marked, neither is there any scooping out, nor lateral expansion of the diaphysis.

When healing commences a line of shadow appears at a short distance from the end of the metaphysis. This line is due to the formation of a zone of provisional calcification, and represents the epiphyseal line in a normal bone; its distance from the diaphysis depends upon the width of the rachitic zone of the osteoid tissue, and varies directly with the duration of the disease. As improvement continues the space between this line and the diaphysis is gradually filled in by bone in the form of striæ; the shadow of the whole bone increases in intensity; and the epiphyseal line become more dense and regular, until eventually the end of the bone shows a normal appearance. The epiphyseal line may remain slightly wavy for some time and the thickened striæ in the diaphysis behind the metaphysis can be distinguished for many months after healing is complete. In some cases of the passive type the first sign of healing is shown by the development of shadows at the margins of the metaphysis, suggesting the development of a mild degree of the cupping which is so characteristic of the active type. As the bone heals the subperiosteal osteoid tissue also ossifies and becomes evident in the radiogram along the shafts of the long bones, particularly the radius, ulna, fibula, and humerus.

Mechanism of the Deposition of Calcium Phosphate as Bone.

This is a somewhat complicated problem, but viewed in its simplest terms we may, with Howland, regard the serum and circulatory fluids as normally saturated or supersaturated solutions, in which the calcium phosphate of bone is in equilibrium with the dissolved salt and this in turn with calcium and phosphate ions. This relationship can be expressed thus:—

$$[Ca^{++}]^3 + [PO_4^{\equiv}]^2 \rightleftharpoons Ca_3(PO_4)_2 \rightleftharpoons Ca_3(PO_4)_2$$

Ionised. In solution unionised. Solid in bone.

An increase in calcium or phosphate ions will cause the reaction to proceed to the right and result in the deposit of bone, whereas a decrease in concentration would result in some of the solid calcium phosphate in bone going into solution, the reaction proceeding to the left. According to mass action law, at equilibrium the product of the concentration on one side of the equation divided by the product of concentration on the other side is constant at constant temperature, and therefore:—

$$[Ca^{++}]^3 \times [PO_4^{\equiv}]^2 = K[Ca_3(PO_4)_2]$$

Now tertiary calcium phosphate is a sparingly soluble salt and in such—

$$[Ca^{++}]^3 \times [PO_4^{\equiv}]^2 = K.$$

This K is called the solubility product constant and whenever the product of the concentration of calcium and phosphate ions becomes greater than the solubility product, solid calcium phosphate will be deposited.

The problem is, however, not quite so simple as this, and at least one other factor must be taken into account—i.e., the presence in the serum of carbon dioxide in considerable concentrations. This has an influence on tertiary calcium phosphate which may be expressed thus:—

$$Ca_3(PO_4)_2 + 2\,H_2CO_3 \rightleftharpoons 2\,CaHPO_4 + Ca(HCO_3)_2 \rightleftharpoons [Ca^{++}] + [HPO_4^{=}]^2 + [Ca^{++}] + [HCO_3^{-}]^2$$

If the carbon dioxide tension of this solution be reduced, the reaction will proceed to the left and calcium phosphate will be deposited if the solubility product is exceeded, as it will be, since the solution is saturated. Now when the plasma substances dicalcium phosphate and calcium bicarbonate, arrive at the osteoid and diffuse into the interstitial spaces the concentration of carbonic acid falls below the plasma level and therefore precipitation occurs.

In rickets the bicarbonate factor is unaltered from the normal, but calcium and/or phosphorus may be. An index of the reduction in the plasma of the material required for calcification could be obtained if it were possible directly to measure calcium and phosphorus ions. Unfortunately, there is no generally accepted method of doing this, but Howland

gested that the product obtained by multiplying al calcium by total phosphorus would serve as an ially reliable index, and formulated the following e. The product of the concentration of phosphorus l calcium in the serum, expressed as milligrammes cent., in the normal child is between 50 and 60; en the product is below 30 rickets is usually present. ien it is above 40 either demonstrable healing is ing place or there has never been any rickets. th products between 30 and 40 rickets is usually sent.

Robison does not agree with the view that the osition of calcium phosphate as bone is purely physico-chemical process, but maintains that the eoblasts and the hypertrophic cartilage cells of the ng animal secrete a very active phosphatase which, hydrolysing the hexose phosphoric esters of the od, brings about a local increase in the phosphate-concentration, with the result that the solubility duct of tertiary calcium phosphate is exceeded l the solid salt is deposited. Together with itland, he has proved the complete absence of this erase from cartilage in the early stage of bone velopment before the beginning of ossification. e beginning of ossification in the embryo is one of the mbling-blocks in Howland's theory, for whilst a urated solution might deposit calcium phosphate coming into contact with solid bone, in embryonic tilage there is no such bone. Howland's theory is more commonly accepted, and his rule is in the in borne out by clinical observations; but it aks down in renal rickets, and in my opinion the cium phosphorus ratio is of even greater importance n the calcium phosphorus product.

Both Howland and Robison hold that rachitic ne is just as able to deposit bone as is the normal ne—i.e., the fault does not lie in the bone but in fluids that bathe it. Robison states that the osphatase can be demonstrated both in rachitic and rmal bone, and Howland bases his argument on ne experiments carried out by Shipley, Kramer, and nself, some of which it was my privilege to see. ces of rachitic bone were placed in blood serum tained from a normal child, or in aqueous solutions taining calcium and inorganic phosphate in which concentrations of phosphorus and calcium proximated to those of normal blood serum. ese were then incubated at 37° C. and after a time ical calcification occurred. Such calcification, wever, did not occur when the slices were placed serum from a rachitic child or in aqueous solutions he concentration of calcium and phosphorus were dequate. Hence rachitic bone tissue is just as le to deposit calcium phosphate as is normal bone sue, and it remains uncalcified only so long as cium and phosphorus are supplied to it in such v ionic concentrations that precipitation of tertiary cium phosphate cannot take place. Rickets, refore, is not a bone disease, and the deformities due to stresses and strains upon a soft bone and really mechanical and not pathological changes.

In the normal infant or young child 100 c.cm. of od serum contains 10–11 mg. of calcium and 3 mg. of inorganic phosphorus, whereas in rickets re is considerable diminution in phosphorus, which y even be as low as 1 mg. per cent. A low serum cium is rarely found with uncomplicated rickets, t does occur in tetany, in cœliac, and, sometimes, renal rickets. In rats, on the other hand, it is ssible to produce rickets associated with either low cium and normal phosphorus (low calcium rickets), normal calcium and low phosphorus values (low osphorus rickets) by feeding respectively with a t that is defective in calcium or in phosphorus. low concentration of either of these two elements he serum can thus occur if the dietary is insufficient, t may also occur even when the dietetic supply is rmal if absorption from the bowel is impaired. If r view is correct, that the ratio of calcium to osphorus is more important than the actual con-ntration, it is possible for rickets to occur even if absorption of both elements is normal, if there is some impairment of excretion. Calcium is chiefly excreted into the large intestine and also to a small degree in the urine. There does not appear to be any primary defect in urinary or intestinal calcium excretion which ensures abnormal calcium retention; indeed, hypercalcæmia induced experimentally soon leads to death. Phosphorus, on the other hand, is excreted chiefly by the kidneys, and here we have a very different state of affairs, since in chronic intestinal nephritis there is phosphorus retention, the calcium phosphorus ratio is altered, and we have a condition which should produce a low calcium rickets, and this in fact occurs (renal rickets).

The modern conception, as I understand it, is, therefore, that rickets is a disorder of calcium and phosphate metabolism resulting from defective absorption (and retention) of these elements from the intestine and rarely from defective excretion of phosphate. As a corollary we can say that rickets can be prevented or cured by taking measures to ensure the normal absorption of calcium and phosphorus from the bowel, and their normal retention in the body.

The questions which recent research has endeavoured to answer are: 1. What are the factors influencing calcium and phosphorus absorption from the bowel? 2. What are the ætiological factors concerned in the production of rickets and how can rickets be cured? These two questions are really interdependent, or are even two ways of asking the same question, but it will be convenient to consider them both and to consider the second before the first.

Ætiological Factors.

Rickets has no single specific constant ætiological factor, but may arise from defective hygienic surroundings, particularly lack of sunshine, or from dietetic causes. There have thus developed two schools of thought—by the one rickets is regarded as a primary dietetic disease, and by the other as due to defective hygiene. The controversy between the protagonists of these theories has been severe, at times even acrimonious, although the results of recent investigation have tended considerably to the restoration of harmonious relations.

The importance of defective hygiene has been emphasised by the Glasgow School as the result of an extensive series of investigations. The hygienic conditions of children suffering from rickets were contrasted with those of normal children in the same social scale and it was shown that the rachitic children were obviously defective in fresh air and exercise, diet being apparently of secondary importance. Two of the Glasgow workers, Hutchison and Shah, investigated the occurrence of rickets in India, and found that, while low caste children did not develop rickets, the disease was common amongst high caste children who lived under the "purdah" system. Late rickets was also common amongst "purdah" women in spite of the fact that their diet and that of their children contained far more fat than did that of the low caste women.

The fact that rickets is a disease of temperate zones and very rarely occurs at high altitudes or in tropical countries, except under the conditions just described, has been known for years. But that this immunity was due to sunlight, and that sunlight could prevent and cure rickets, has only been generally recognised recently, although as long ago as 1890 Palm drew attention to the importance of sunlight in this connexion. The value of sunlight was, however, not appreciated until Huldschinsky, in 1919, showed that rickets could be cured by the action of ultra-violet rays, and Hess and Unger, in 1921, conclusively demonstrated the cure of rickets by sunlight. Although Findlay regarded lack of exercise as being the essential factor of defective hygiene, the balance of evidence points very strongly to the conclusion that the results of defective hygiene are in reality due to lack of sunshine.

Since the original statement of Kassovitz in 1884 many observers have commented upon the seasonal

incidence of rickets. The greatest incidence of the disease is in the late winter and early spring months—e.g., January to May—but the seasonal variations are much more marked in countries with a considerable amount of sunshine, such as Canada, the United States of America, and Austria, than in countries like the British Isles in which, indeed, the seasonal variations are not very obvious. It is interesting to note that coincident with the seasonal incidence of rickets there is a seasonal decrease in the calcium and phosphorus of the blood. Recent observations by Brown and Tisdall, in Toronto, have shown that there is a sharp rise in the antirachitic effect of sunshine about the beginning of March, and that the antirachitic effect of April and May sunshine is about eight times that of December, January, and February. The same investigators also found that a considerable amount of ultra-violet irradiation takes place as a result of reflected rays from the sky and clouds, the antirachitic effect of which is approximately one-half to two-thirds of that produced by what is ordinarily termed sunshine—namely, direct rays from the sun plus reflected rays from the sky. All ultra-violet rays are not of value in preventing or curing rickets. In sunshine the most effective rays are the shortest, the wave-length of which ranges from 2900 to 3130 Angstrom units. Unfortunately, in those industrial areas of the British Isles where rickets is prevalent sunshine is somewhat rare, and any that may occur is almost valueless either for prevention or cure, since the smoke pall cuts off the ultra-violet rays. Moisture of the atmosphere, such a constant feature of our climate, also cuts off many of the rays. When the atmosphere is heavy with moisture, or polluted with smoke or dust, waves shorter than 3000, or even 3100, Angstrom units may be absorbed (Hess and Anderson.)

Ordinary flint window glass completely cuts off all the curative ultra-violet rays, and, therefore, several substitutes for window glazing have been invented. The one best known in this country is Vita glass, which transmits rays down to 2900 Angstrom units. Tests on rachitic babies carried out in Boston, U.S.A., by exposing them to winter sunshine near windows, showed that Corning glass and quartz glass transmitted enough ultra-violet rays to cure rickets in very black babies, but whilst Vita glass transmitted light waves to the extreme limits of the sun rays, it did not transmit them in sufficient quantities to be of use in healing black babies during the winter months, but the observers thought that better results could be obtained if longer exposures to the sun rays were given. There are two differences between Boston and this country. In the first place, it is a city with very much less smoke than our industrial cities; and, secondly, the question of black pigmented babies is one of little importance here. Vita glass is unquestionably of value in country districts, but in my opinion it is practically useless in smoky cities.

Antirachitic powers can be conferred on certain foodstuffs by exposing them to the action of ultra-violet rays. Thus milk in both liquid and dried forms, wheat, and vegetables, such as spinach, carrots, &c., have been rendered antirachitic. On further investigation this property was found to be due to the activation of certain sterols, cholesterol in the animal, phytosterol in the vegetable compounds, and the administration of irradiated cholesterol and phytosterol was found to protect rats from rickets. Active cholesterol was also found to give a characteristic absorption spectrum in the ultra-violet region. The effect of administering irradiated cholesterol to children suffering from rickets was subsequently tried at the Children's Hospital, Birmingham, and we had the privilege of demonstrating the complete and rapid cure of a case of severe and resistant rickets. The details may be of some interest because the clinical experiment was controlled as carefully as possible.

The patient, aged 3 years, had received treatment by cod-liver oil from April to September, 1925—i.e., during the spring and summer months. He was admitted into hospital in September and for one month did not receive any antirachitic treatment, but was placed on the full hosp dietary. Radiograms taken 14 days after admission sho a slight degree of healing when compared with that ta on admission, possibly due to the effect of the cod-l oil taken before admission, but no further healing of moment occurred between the fourteenth and twe eighth days.

The child was then given 1 drachm three times a of a 3 per cent. solution of irradiated cholesterol in lins oil for a few days, and then the dose was increased 2 drachms three times a day. In three weeks considera healing had occurred, and complete healing was noted 11 weeks.

The points to notice are: (1) that the case was of a group of rickets which is somewhat resistant cod-liver oil therapy; (2) that a period was allow before starting cholesterol treatment, so that t effect of any delayed healing from cod-liver oil w eliminated; (3) that cure was produced in t autumn and winter months.

Later we used irradiated cholesterol in pow form in the treatment of cœliac disease, with a without rickets, with most encouraging results. T cholesterol used was chemically pure cholesterol a was irradiated by the method suggested by Hess.

The antirachitic power of irradiated choleste diminishes after a time; also, unless certain p cautions are taken, such as the removal of the ozo generated, prolonged irradiation renders choleste inactive again. We also found that some of t batches of irradiated cholesterol did not appear be as potent as others. As a result of certain exp ments, Heilbron, Kam, and Morton came to the c clusion that not cholesterol itself, but some substa associated with it is activated by irradiation, a Rosenheim and Webster found that chemically p cholesterol, prepared by formation of its dibro derivative and the reduction of this to choleste again, developed no antirachitic power after irrad tion. These workers showed that only choleste obtained from natural sources—i.e., bile, brain, &c could be activated, but they came to the conclusi that the impurity itself must be a sterol since formed an insoluble compound with digitonin. was suggested by Windhaus that this sterol might ergosterol, obtainable from ergot, yeast, &c., beca it was the only known sterol having a struct likely to give it the required properties. Ergoste was therefore investigated by them and also by H and was found to develop intense antirachitic pow on irradiation, being about 2000 times as strong ordinary cholesterol, and it, or a sterol closely simi to it, is now regarded as the impurity which activated when natural cholesterol is irradiat Ergosterol when irradiated is the most powe antirachitic substance known; 1/10,000 mg. protect rats from rickets, and it is estimated t 5 mg. are equivalent to 1 litre of the best cod-li oil known. Irradiation leads to an obvious physi change in ergosterol, a yellowish resin being produc How much of the substance is actually activated not known, and it is possible that further experime may yield more intensely antirachitic substances.

Diet and Vitamins.

In the clinical study of rickets two facts st out. First, that the condition often develops children who are fed on a diet rich in carbohydra but poor in fat, such as condensed sweetened skimm milk and many proprietary foods. Secondly, t in most instances it can be cured by the exhibit of cod-liver oil.

In 1918 Mellanby suggested that rickets might due to the absence of an accessory food factor, a later stated that this antirachitic factor was proba identical with vitamin A. In his view cod-liver had the strongest, and vegetable oils scarcely a antirachitic action. Milk and yolk of egg contai a large amount of antirachitic substance. Mellanb experiments and conclusions were, however, critici adversely by many people. During the war Denm exported large quantities of butter to Germany, w the result that poor people were unable to buy wh

r. Skim milk, however, was easily procurable was largely used for the feeding of infants. As a lt many of these children developed nutritional rders (dystrophia alipogenetica) often associated n xerophthalmia, which, in many instances, passed o total blindness. The proof that this condition due to lack of fat was forthcoming when the ish Government took over the supplies of butter, oned it, and allowed 250 g. weekly to each vidual, with the result that xerophthalmia ediately ceased. Bloch, who described these s, emphasised the fact that in spite of the absence at these children rarely developed rickets, and he cluded that absence of vitamin A caused xeroph-mia but did not produce rickets. By feeding on a diet deficient, amongst other things, in rickets and xerophthalmia can be produced erimentally.

n 1920 Gowland Hopkins showed that it was sible to destroy vitamin A in butter and cod-liver by heat and aeration, and in 1922 McCollum and co-workers found that cod-liver oil so treated uld no longer cure experimental xerophthalmia would cure rickets. It appears clear, then, that ely associated with vitamin A is another fat-ble vitamin which has antirachitic properties, this is called vitamin D. Cod-liver oil is a good rce of both vitamins, but cow's milk, whilst rich vitamin A, is a poor source of vitamin D. The that some fats contain considerable amounts of min A and but little vitamin D is the probable lanation of the failure of some workers to confirm llanby's experiments.

t is probable that the curative action of sunlight artificial ultra-violet irradiation in rickets is due the synthesis of vitamin D by the activation of osterol, or some similar sterol, found in association h cholesterol in the skin. Indeed, irradiated ergo-ol is so potent that it has been suggested that it pure vitamin D. Evidence that irradiation does duce vitamin D *in situ* is found in the fact that s fed on a dietary producing the low phosphorus e of rickets develop an alkalinity of the fæces, pH of which can be reduced, even to the acid e of neutrality, by irradiation or by the administra-n of irradiated ergosterol or cod-liver oil. Further dence that irradiation of the cholesterol (or ergo-ol) of the skin has a curative action is found in the ervation of Hume, Henderson-Smith, and Lucas t inunction of irradiated cholesterol into the skin abbits and rats fed on a rickets-producing dietary vented the development of rickets.

Whence comes the vitamin D present in cod-liver ? It has been stated that this is obtained from the n algæ and diatoms (plankton) in the upper waters he ocean, and that in these vitamin D is synthesised ler the influence of sunlight. This plankton consti-es the food of small fish, which in their turn form diet of the cod, and in the latter the vitamin is gely housed in the liver. The most recent researches, wever, show that, whilst the marine diatom is a n source of vitamin A, it contains no vitamin D, l the suggestion has been made that, both in tion to green plankton and green vegetables, ich contain much vitamin A but little or any D, same mistake has been made as in the earlier work Mellanby on fats when no differentiation was made ween the A and D vitamins. Moreover, Bills has wn that the principal food of the Newfoundland is the caplin, but that this does not contain enough min D to account for the amount of vitamin ich is accumulated by the cod during its mid-mmer period of fattening, and he therefore suggests t the vitamin may be synthesised by the cod.

The exposure of an animal to sunlight raises the tent of vitamin D in its milk, and for this reason w's milk shows a seasonal variation in vitamin D tent which is related to similar seasonal variations he incidence of rickets. The content of vitamin D, wever, is not greatly increased by sunlight, but can, the other hand, be considerably augmented by posing the animal to ultra-violet rays from artificial sources, although such milk will not compare in anti-rachitic power with milk irradiated directly. It seems evident, therefore, that during the winter months breast milk must be considerably poorer in vitamin D than in the summer. However, it has been proved, as in the case of cow's milk, that the anti-rachitic properties of human milk can be increased by the irradiation of the mother, and that if cod-liver oil be given to her, the vitamin D can pass into her milk. Although it is a matter of universal clinical observation that rickets is far less common in children who are breast-fed, the question of the antirachitic effect of human milk and its relationship to vitamin D is one of great interest and difficulty. This difficulty will become even greater if confirmation is obtained of some recent experiments of Hess, from which he concludes that human milk is exceedingly poor in the antirachitic substance, and that its high protective power in rickets cannot be ascribed to that factor. McCollum states that animal experiments make it clear that faulty nutrition of the mother during pregnancy and the early part of the nursing period may so debilitate her young that later a diet which should protect against rickets may fail to do so, and, according to Greenbaum, if the maternal diet during the last three months of pregnancy is made approximately correct in caloric and mineral intake, rickets will not be absolutely prevented, but the mother's diet will have a controlling influence in the development of the disease in the offspring.

Rickets, however, does frequently occur in breast-fed premature children, twins, and particularly in dark-skinned Italian and negro children living in North American cities. Prolongation of breast-feeding into the second year of life is also very liable to produce rickets. The conditions under which Eskimo children live are of great interest in this connexion. In Greenland rickets does not exist, despite the fact that children are nursed until the age of 2 to 4 years, whereas in Labrador, although the children are much more exposed to sunshine, rickets is almost universal. The Greenland Eskimo, contrary to popular belief, eats little fat, but partakes freely of uncooked fish, birds, seals, &c., and the freedom from rickets is probably due to the presence in this diet of considerable quantities of vitamin D derived from the fish on which the birds and seals feed. The Labrador Eskimo, on the other hand, cooks his food, a large proportion of which is prepared or tinned, and eats very little vegetables (Thomas).

Calcium and Phosphorus.

From what has previously been stated, it is obvious that another important factor in the dietary is an ample supply of calcium and phosphorus. Adequate supplies of vitamin D or sunshine will prevent or cure rickets even when a baby is taking a diet which, from deficiency in calcium, phosphorus, or vitamin, would otherwise produce rickets.

Of all the factors concerned in the prevention of rickets, exposure of the body to sunshine and the preservation of the natural habitat of the child and diet of the mother are probably the most important. As clothing increased, and with it the urbanisation of society, the migration into cities and darkened dwellings, or, as in the case of the negro peoples, if movement occurred into more temperate zones, or, as in the case of the Labrador Eskimo, the maternal diet so changed that the supply of vitamin D diminished, rickets developed even in breast-fed children, but with more certainty in those artificially fed. Thus we have the appearance and development of rickets associated with the progress of civilisation, and in particular, with the rise of industrialism and the decline of breast-feeding.

As a result of these recent advances in our knowledge of the ætiology of rickets, the question may well be asked: was Glisson right in his view that rickets was a disease which had made its appearance for the first time but a few years before his monograph was written? It is true that the factors necessary for the production of rickets have been present, at

least in Europe, since ancient times, although there is no reference to rickets in Hippocrates, Galen, or Celsus. Soranus of Ephesus, a physician who practised in Rome during the second century A.D., wrote thus :—

> The infant's feet become deformed from unwise attempts at walking. Frequent examples of such deformities are seen in Rome, due in most cases to ignorance and improper care of the infant. City women devote much less care to their infants than those in rural districts, hence the more frequent occurrence of these deformities among the infants of city dwellers.

Surely Findlay is justified in regarding this as a description of rickets. We have, however, even more positive evidence that rickets existed 200 years before Glisson's time, for in the paintings of the fifteenth century artists of the Netherlands and Germany, especially those dealing with the Nativity, clinical evidence of rickets can be seen. In our own National Gallery there are several pictures of this type, but I will only mention one painted by the Netherlands artist, Dirk Bouts, in the year 1490. This picture shows definite evidence of rickets, not only in the child but also in the mother, whose forehead is an excellent example of Parrot's nodes. Anyone can multiply examples of this kind by exploring the galleries of Amsterdam, The Hague, &c. It is quite clear that in choosing models for such a subject the artist would not wittingly select those showing the stigmata of disease, but rather those approaching his ideal of perfect physical development. It is surely, therefore, a logical conclusion that in the fifteenth and sixteenth centuries, when the privations of war were frequently experienced by dwellers in the Low Countries, rickets was a common condition in the industrial cities of Holland and Germany (Foote).

CARCINOMA OF STOMACH.*

By A. J. WALTON, M.S. Lond., F.R.C.S. Eng.,
SURGEON TO THE LONDON HOSPITAL.

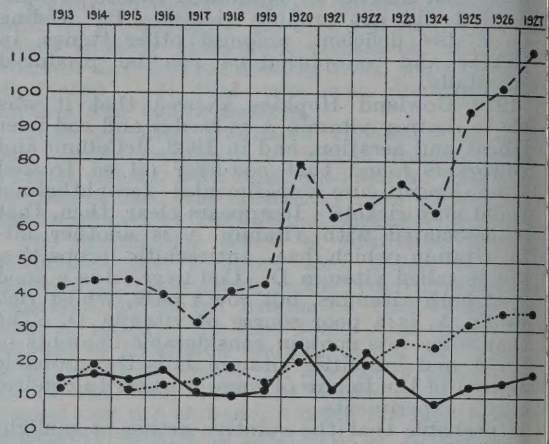
In the public mind there is a belief that cancer is not only uniformly fatal, but that it is rapidly increasing in frequency. Recent careful investigations have shown that this view is too pessimistic, and it has become quite evident that the different varieties of carcinoma vary considerably in their severity, many examples being permanently cured if subjected to early operative intervention. Of these varieties carcinoma of the stomach must, however, be considered one of the most unsatisfactory, for the early diagnosis is associated with much difficulty, and the late prognosis, as shown by more careful follow-up records, is not nearly so good as was at one time believed. It is therefore all the more satisfactory to note that there is little or no evidence that the disease is on the increase. Such a belief is based upon the returns of the Registrar-General, but these are probably of doubtful value, for with improvement in diagnostic methods cases are included that were previously omitted, and it is almost certain that many others are recorded as carcinoma when the diagnosis has not been confirmed by microscopic investigation. My own figures concern patients who have all been subjected to operation, and the diagnosis has therefore been proved either by visual inspection or by microscopical examination, confirmed in all cases by a careful observation of their after-progress. Thus, although small in number, they are of considerable interest. There has been little or no increase in the numbers operated upon year by year, whereas the proportion of cases of carcinoma to those of other lesions of the stomach has shown a very marked decrease. From 1913 to the present date the total number of cases of carcinoma of the stomach that have come to me for operation has been 229, and the total number of simple chronic ulcers 1086, the carcinomata thus forming about 17 per cent. of the total.

* Being a communication made to the International Cancer Conference, recently held in London.

In other words, of every six gastric operations c is performed for carcinoma of the stomach. T numbers of these lesions operated upon each yea shown in Fig. 1. This chart shows clearly t whereas the number of ulcer cases operated up has multiplied nearly three times the number carcinomata has remained nearly constant year year.

Of more importance than the relationship to t total number of ulcers is that to ulcers of the bo of the stomach, for it is this variety which is r

Fig. 1.



Frequency of carcinoma and chronic ulceration. Total ca of carcinoma 229 (males 166, females 63); total cases chronic ulcer 1086 (males 824, females 262).

In both figures the continuous line indicates "carcinoma," t interrupted line "all ulcers," and the dotted line "les curve ulcers."

only more likely to become carcinomatous, but most commonly confused with carcinoma eitl before or during operation. Duodenal ulcers, on t other hand, may be said never to become carcinom tous, and it is this variety which has shown t greatest increase. Nevertheless, lesser curve ulc are nearly three times as frequent in my prese practice as they were in 1913.

It must be remembered that these figures, occurri as they do in the practice of one surgeon, are evidence of an increase in the number of chro ulcers in the general population, but since the ulc have so greatly increased in number a correspondi increase would be expected in the numbers of carci mata, and since it has not occurred it would sugg that carcinoma of the stomach is becoming a l frequent disease. The only explanation I can of is that of recent years our work has been, as should always wish it to be, preventive, and th many patients have been saved from carcinoma having their ulcers treated surgically while they a yet benign.

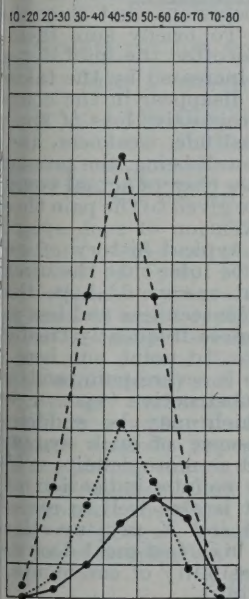
The sex relationship of the two conditions sho that whereas both carcinomata and ulcers are mu more common in the male, this frequency is more evidence in the ulcers than in the carcinoma Thus, of the 229 cases of carcinomata, 166 occur in males and 63 in females; whereas of the 10 ulcers, 824 were males and only 262 were femal There is also a distinct difference in the age-frequen Carcinomata of the stomach is found most commo between the ages of 40 and 70, the majority bei present between 50 and 60; whereas the ulcers a more frequently detected earlier, being seen m commonly between the ages of 30 and 60, and wi the greatest frequency between 40 and 50. In Fig the frequency of these lesions in the different decad is made apparent.

Results of Operation.

The operative treatment of carcinoma of t stomach has now been sufficiently long in vogue t

to obtain definite figures of the end-results. It thus be more valuable to consider whether we satisfied with these results before discussing how may more readily make an early diagnosis or prove the technical details of our treatment. en consulting the literature on this subject, there ound to be an extraordinary difference of opinion to the value of surgical treatment. The early res of Friedenwald [2] gave a most gloomy prog-is, for he found that of 1000 cases, only nine were able of having a resection, and not one case was ed thereby. Cheever [1] also found that in a series 236 cases, radical operation was only possible in per cent. Many later figures give a much more eful outlook both as regards the possibility of orming a partial gastrectomy and of the ultimate -results. Mayo [5] has estimated that a correct gnosis should be made sufficiently early to permit least 50 per cent. of radical operations, although is own series the actual number in which a partial rectomy was possible was about 35 per cent. also showed that out of 651 resections of the nach, 38·6 per cent. were alive three years or e, and 26·5 per cent. were alive five years or more r operation. Paterson [6] also states that 24 per . of cases were alive and well three years after ration, and 15 per cent. after five years. Hayem [4] nd that of 100 cases, 28 passed the three-year od without recurrence. I have given these ervations at some length, for nine years' experience a carefully controlled follow-up department has steadily strengthened my opinion that these later figures are much too optimistic, an opinion which I am not alone in holding. Gibson,[3] in a most valuable investigation in New York, states that "no sadder report of the disheartening status of cancer surgery has come to our attention." Of 70 cases of carcinoma of the stomach he found only one alive and well after five years, and also one only after three years. I regret to state that this experience is much more in accord with my own. It is true that we are all of us conversant with cases which have lived many years after operation. Hayem,[4] for instance, reports one who lived for 27 years, and Pearce Gould,[7] one who lived for 18 years and then had a recurrence. I also have seen a case operated upon by Mr. Hugh Lett in 0, when I was his registrar, which was proved microscopic examination, and who was readmitted 927 with an anæmia of the pernicious type which ht or might not have been due to a recurrence. h cases are, however, exceptional. In reviewing own series the large proportion of inoperable es is very startling. Of the 229 cases it was only sible to perform a partial gastrectomy in 78, that 33 per cent., a proportion probably smaller than ound with any other variety of carcinoma. It is, vever, in the progress of these cases subjected to at is hoped to be a radical cure that so much appointment lies. I have been making for the tish Medical Association a careful analysis of the es operated upon by myself in the years 1920–24 usive, and for the purpose of this present investiga-n I have added those cases operated upon before 1920. All the cases, therefore, have been operated upon for four or more years. They number in all 177, of which 62 were subjected to partial gastrectomy. Of these, three cannot be traced, one is well 15 years, one—the only sarcoma in the series—well 12 years, one well ten years, and one seven years after operation (see table).

FIG. 2.



-incidence of carcinoma and chronic ulceration.

Cases operated upon 1913–24	177
Partial gastrectomy	62
Not traced	3
Died of recurrence	55
Alive	4
(15 years, 12 years, 10 years, 7 years = 1 each.)	
Total cases (1913–28)	229
Secondary to ulcer	25
Diagnosed as ulcer before operation	55

The remainder have all died with recurrences, some of which only appeared three or four years after operation, and although it is true that many patients have been given two or three years of happy life in place of the three to six months' misery, which would occur with no operation, yet these results must be regarded as being among the most depressing in surgery. In placing these figures before you, I at once lay myself open to the charge of having performed incomplete operations. It may be said, and it probably will be said, that such poor results could only be obtained by insufficient removal of the stomach or glands. It may only be my conceit that makes me believe that this is not the true explanation, but in many cases a very wide resection indeed has been carried out so that it would best be described as a subtotal gastrectomy, and I am very doubtful if a wider removal could have been effected. Moreover, in nearly all the cases recurrence has later taken place either in the liver or in the deep cœliac glands. Therefore I feel certain that improvement in the late results does not lie in more extensive operations, and also that the figures I have put before you give a more correct picture of the results obtained by surgical treatment than many that have been published.

Improved Diagnosis.

In attempting to better our results, it is at once evident that improvement is to be looked for along two lines. The fact that only one-third of the total number of cases are operable is evidence that correct diagnoses are not being made sufficiently early. A large number of my patients have been under medical treatment for prolonged periods, often in the belief that a simple ulcer was alone present, a point to which I shall have to return later. This is, however, only applicable to a certain number. One of the greatest difficulties with which we have to contend is that in not a few cases the symptoms are at first so slight and ill-defined that the patient either seeks no treatment, or attempts to improve his symptoms by the use of domestic remedies, only seeking skilled advice a few days before operation, at which time the disease is already hopelessly inoperable. It is, indeed, difficult to see how any improvement can be made with this class of case, for it is not feasible to suggest that apparently healthy people should, after the age of 40, have routine examinations which would have to include a test-meal and the use of X ray investigations. Some improvement may, however, be expected in this direction if doctors will remember and if the public can be made to realise that any persistent dyspepsia occurring after the age of 40 in a patient with a clear past history is to be regarded as due to carcinoma until this disease can be definitely eliminated.

Malignant Change in Gastric Ulcer.

It is, however, along the second line that the greatest improvement is to be expected. For many years Sir Berkeley Moynihan and others, including myself, have been laying stress upon the fact that a certain number of cases of gastric ulcer tend to

become carcinomatous, and thus the improvement in the results of operation for carcinoma of the stomach lies in operating upon the ulcer in its still benign period. In the United States of America this relationship is well recognised, but unfortunately in this country there has been a tendency of late to belittle the relationship between the two lesions; probably this has in part been due to the fact that in the past it was claimed that the majority of cases of carcinoma commenced as chronic ulcers, a view which wider experience could not support, and hence there is a tendency for the pendulum to swing in the opposite direction. The denial of such a relationship has, however, gone hand in hand with extravagant claims for the value of medical treatment, and this of necessity, for if chronic ulcers may become carcinomatous it will clearly be inadvisable to subject them to prolonged periods of such treatment. It is also unfortunate that the lay press has widely circulated the view that all chronic ulcers can be cured by medical treatment, for there is now a tendency for patients to postpone operation and to undertake a prolonged course of medical treatment, a procedure which I feel convinced will lead to an increase in the number of cases of carcinomata of the stomach, and will undo much of the preventive treatment for which surgeons have striven so long.

In my own series of cases there has been very definite evidence that a certain number of cases of carcinoma have started as chronic ulcers. I have only placed in this group those that have fulfilled the following requirements:—

1. They must all have had a history of many years' standing in which the earliest symptoms were periodic.
2. They must all at the time of operation have had a relatively high test-meal.
3. The appearances of the lesion at operation must have suggested the presence of a chronic ulcer. In some cases, indeed, the diagnosis of chronic ulcer to the naked eye appeared to be definite.
4. The pathological report must have shown that the carcinoma was almost certainly secondary to an ulcer.

In my own series of 229 cases there were 25 examples which conformed with these requirements, and these, of course, do not include any examples which had progressed so far that a radical operation was not possible, or those which had led to a complete achlorhydria. Hence, this figure probably much underestimates the frequency. They are of special importance, for it is in such cases that a radical cure is most to be expected. My patient, who is alive and well seven years after operation, was only recognised to be a case of carcinoma after the microscopic examination, but a partial gastrectomy was carried out on suspicion owing to a slight alteration in the symptoms. She was therefore treated at the earliest possible stage. Of equal importance with this group are those cases which are definitely but erroneously diagnosed as simple chronic ulcers before operation, for it is these cases especially in which medical treatment is likely to be continued and the opportunities of early operation are lost. I have elsewhere pointed out that since the recent vogue for medical treatment four such cases have come to me when the carcinoma was hopelessly advanced. In my own series there were 55 such cases, a percentage of nearly 25 of the total. These had been definitely diagnosed by physicians of wide experience and repute as simple chronic ulcers, and it was only at operation that the evidence of carcinoma was forthcoming. To my mind, therefore, there can be no question whatever that the hope of greater success in the future lies not only in a wider recognition of the early symptoms of carcinoma, but also in the acceptance of the belief that chronic ulcers in patients between the age of 40 and 60 should be subjected to early operative treatment, and should not be treated medically for a long period of time. It is probably owing to such a course of action that my figures show no increase but rather a definite relative decrease in the frequency of carcinoma of the stomach, and every effort must be made not to lose this advantage.

Early Symptoms and Early Treatment.

In the recognition of the important early symptom special stress must be laid upon the fact that afte perfectly clear past history the majority of patie have developed a dyspepsia persisting for two or th weeks. I have always taught, and I am confid that it is correct, that if there is no definite error diet to account for such a group of symptoms, th patients should be regarded as carcinomatous unl definite evidence can be produced to show that th are suffering from some other lesion. It is perfec true that occasionally, if such a dictum is accept a patient will be operated upon and will be found be suffering only from a gastritis, possibly of atonic type due to overwork and worry; a care investigation will, however, often eliminate such condition. In the few remaining cases it has b my experience, much as I deprecate the use of exploratory laparotomy, that such patients are pleased to find that they are not suffering from carcinoma that they will only too willingly put with the drawbacks of an unnecessary laparotor I have been honoured by having been asked operate upon a large number of medical men, and th patients, who are those best able to realise the dra backs of operation, have been only too willing to f the possibility of an unnecessary laparotomy if in end they can be assured that no carcinoma is prese and it would seem self-evident that the line of cond which a medical man would choose for himself is one which he can best advise his patients to foll Of the individual symptoms of the different varie of carcinoma I shall say but little, for these have b described upon so many occasions that they sho now be well recognised. To briefly sum them they are the constancy and often the mild degree the pain, which, although increased by the taking food, does not completely disappear in the course the day, the steady and progressive loss of appet the increased feeling of lassitude, weakness, and loss of the usual feeling of well-being, the presence frequent regurgitation rather than of actual vomiti and the failure of relief to be given to the pain there It is especially the supervention of such sympto upon a case presenting a typical history of gas ulcer which would lead us to infer that the ulcer become carcinomatous, but one would hope that the future this change will be seen less and less as long-persistent ulcers are more frequently treated operation. It is well, also, to point out here t cases are seen where there is severe pain, and wh there is vomiting of the obstructive type, or wh there is hæmatemesis which may be sudden severe, and that the presence of such sympto which are usually regarded as more definite evide of a gastric ulcer, are no counter-indication of presence of carcinoma. It is also well to remem that although a test-meal and X ray investigat are of very great value, a high test-meal does no necessity eliminate the possibility of carcinoma, neither does a negative X ray.

Such symptoms occurring in a patient o 40 must always be regarded with the most gr suspicion, and it is by the recognition of th importance that one must hope to obtain be results in the treatment of this most danger and depressing variety of carcinoma. Although present but few cases have been cured by operat treatment, there can be no question but that a sm percentage are so cured, and of this benefit ev patient must be given the advantage at the earl opportunity, for all other methods known to us present, such as the use of radium and deep X therapy, are—useful though they may be—no m than palliative procedures. It must also be rem bered that whereas cases which are not operated u have an average expectation of life of only three six months, those who are treated by partial gast tomy not infrequently live for three or four years happiness and comfort. In my own series, 15 c showed evidence of recurrence only between

nd and third year, five between the third and th year, and two after four years. My chief on for putting these figures before you, however, impress upon you my belief that in this, as in r branches of medicine, the greatest progress has and is still to be made by the use of preventive sures. An understanding of the cause of carci- a implying, as I believe it does, a knowledge as hy a cell reverts from its unipotential character totipotential phase, still seems far from us, and that time arrives, the greatest hope of preventing inoma of the stomach lies in the free surgical oval of all chronic ulcers. If the lay press, alter- their present views, will help us with the great ht of their authority to teach the public that the rity of such ulcers should be excised, much will ccomplished in diminishing the frequency of this d disease.

SYPHILIS OF THE ŒSOPHAGUS.

WITH A REPORT OF TWO CASES.

By A. LAWRENCE ABEL, M.S. Lond., F.R.C.S. Eng.,

EON TO THE KENSINGTON GENERAL AND LONDON LOCK HOSPITALS; ASSISTANT SURGEON TO THE WOOLWICH WAR MEMORIAL HOSPITAL, ETC.

YPHILIS of the œsophagus is only diagnosed in or two of every 1000 cases presenting them- es with an œsophageal lesion. It occurs, however, ll cases of acute syphilis which remain untreated l the so-called "secondary" stage is established, only as a part of the general inflammation of all ous membranes, and usually there is a complete nce of any œsophageal syndrome. It is not until condary œsophagitis is present, or a spasmodic rganic stenosis appears, that cases of syphilis he œsophagus come to the hands of the œsophago- ist for diagnosis and treatment. I shall confine e remarks, therefore, to a description of syphilis the œsophagus accompanied by the cardinal ptom of dysphagia.

Pathology.

yphilis of the œsophagus occurs rarely in the genital form of the disease. More commonly, he so-called "secondary" stage, it may give rise n œsophagitis, of such severity as to be manifested dysphagia. The condition rapidly responds to ropriate treatment, and is very seldom followed stenosis.

During the so-called "tertiary" period syphilis he œsophagus is still more common, and takes the n of localised gummata. The gumma usually es in either the upper or lower third of the canal, on rupture produces a typical gummatous ulcer h a clearly cut edge and an unhealthy yellow base. re is considerable local induration, which, together h the concomitant spasm, is the main cause of obstruction to the lumen. Leukoplakic patches y occur in the neighbourhood; some local non- cific œsophagitis may be present, together with ttle hypertrophy of the wall and dilatation of the phagus above the level of the lesion.

Diagnosis.

The symptoms are those of painless dysphagia, together with those of any other syphilitic lesion which may coexist. If, however, there is any pharyngeal lesion, painful dysphagia occurs, together with some local spasm and regurgitation.

The previous history of a case is important, and leading questions must often be asked. The history of swallowing a corrosive or caustic or excessively hot fluid, or of an impacted foreign body, especially a tooth-plate, leads the clinician to doubt the existence of a true syphilitic lesion even in the presence of positive serological tests, and is more suggestive of a simple cicatricial stricture. The same is true of dysphagia following closely upon diphtheria or typhoid fever.

The duration of the dysphagia and its mode of onset is not of great value as an aid to an accurate diagnosis except when there is a definite history. Nevertheless, certain general facts should be borne in mind. Dysphagia in a case of syphilitic stenosis has usually lasted from four to twelve months before a careful examination reveals the true nature of the lesion. During this time the patient may or may not have been treated by his own medical practitioner for "indigestion," "gastritis," "gastric ulcer," "globus hystericus" or "nerves." Dysphagia of many years' standing, in the absence of a history indicative of simple stricture, is more suggestive of cardiospasm, but can be produced by a pharyngeal pouch, an œsophageal pouch, a fibrosis in the region of the crico-pharyngeal sphincter, a congenital stenosis of the œsophagus, or even by a syphilitic lesion. The onset of specific dysphagia is almost invariably gradual. Sudden difficulty in swallowing is more suggestive of an impacted foreign body or even of a malignant growth.

When syphilitic stenosis of the œsophagus is present there is usually nothing to distinguish it from any other variety of stricture except direct local examination. General examination will frequently reveal that the patient is suffering from syphilis, and there will be no clinical signs of malignancy, such as Virchow's glands. Especial attention should be paid to the mouth and throat, as signs of leukoplakia of the tongue or inner side of the cheek are rarely absent in long-standing cases. Scars are often found on the legs, and bilateral enlargement of the epitrochlear lymphatic glands, with no local condition to account for it, is always present.

Radioscopy.—After a complete general examination of the patient radioscopy is employed in order to exclude the presence of an aneurysm or other intrathoracic cause of extrinsic pressure upon the œsophagus, and to determine the level of the lesion.

Œsophagoscopy should next be resorted to, and great difficulty may be met with in making a purely visual diagnosis. This is especially so in the non-ulcerated variety of gumma, which closely simulates an infiltrating carcinoma. An actual ulcer is more readily diagnosed, and a portion removed for microscopical examination may reveal the true nature of the disease. The diagnostician must not be led astray by a negative Wassermann reaction of the blood, which is given by a very large proportion of sufferers from tertiary syphilis. The pathological examination of the cerebro-spinal fluid will, however, almost invariably confirm the clinical diagnosis of syphilis in this stage. On the other hand, a positive Wassermann reaction must not be taken to indicate that the condition is non-malignant, and therefore biopsy must always be performed. If in a doubtful case this fails to prove suspected malignant disease, it should be repeated. After two or more microscopic examinations have failed to reveal the true cause, and in the absence of a history indicative of a simple stricture, syphilis is to be strongly suspected. The diagnosis is usually confirmed by appropriate treatment.

I wish most strongly to emphasise that syphilis of the œsophagus must not be diagnosed by symptoms and serological tests alone, because many patients who have carcinoma of the œsophagus have also active syphilis. As I have shown elsewhere,[1] it is most important that cancer of the œsophagus should be treated at the earliest possible moment; direct œsophagoscopic examination must, therefore, be made in all cases with symptoms of an œsophageal disease.

FIG. 1. FIG. 2.

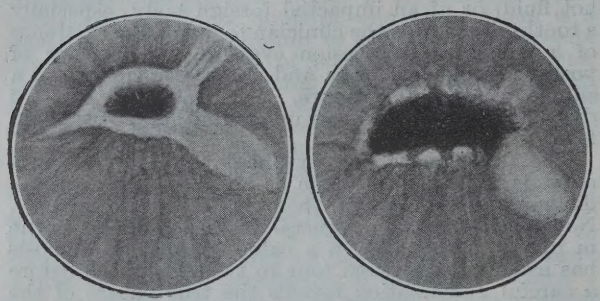

FIG. 1 (Case 1).—Syphilitic stricture of the œsophagus (cervical region) as seen through the œsophagoscope before treatment.
FIG. 2 (Case 1).—Seven days after dilatation with bougies.

Treatment.

Treatment is undertaken along two lines: (1) Anti-syphilitic treatment; (2) œsophageal treatment to combat the actual or potential stenosis.

1. In acute syphilis, arsenic is administered intravenously for eight weeks, provided it has not been previously used in large quantities in the same patient. If it has, then only a shorter course of arsenic should be given. The dose varies from 0·45 to 0·6 g. in the female, and from 0·6 to 0·9 in the male, at weekly intervals. At the same time as the arsenical injection an intramuscular injection of mercurial cream or bismuth is given. At about the middle, and at the end of this course of treatment, an intramuscular injection of 0·25 g. of contramine should be given. After the last injection of contramine the patient is allowed four weeks' rest from injections and given potassium iodide grs. 5 in plenty of water, three times a day by the mouth. After this, intramuscular injections should be recommenced, and continued once a week for eight weeks. They may consist of either gr. 1 of mercury as a mercurial cream given each week, or 0·2 g. of an oily suspension of bismuth. By far the best preparation of bismuth in my experience is iodo-bismuthate of quinine (Fraisse), and this may be used with benefit alternately with the injections of mercury. After eight injections the patient is given four weeks' treatment by medicine—either potassium iodide as before, or collosol sulphur, 1 drachm three times a day; then eight weeks on a heavy metal and four weeks on a non-metal, and so on. The arsenical treatment should not be repeated.

FIG. 5.

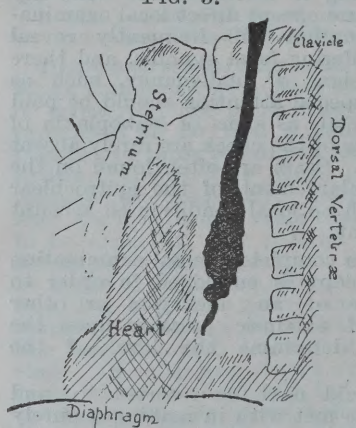

FIG. 5 (Case 2).—Diagram of radiogram of syphilitic stricture of œsophagus after swallowing radio-opaque emulsion.

[1] Abel, A. L.: The Treatment of Cancer of the Œsophagus, Brit. Jour. Surg., 1926, xiv., 53, p. 131.

In secondary syphilis this treatment should be continued for at least three years, and no note whatever need be taken of the Wassermann reaction, whether positive or negative, during this time. In tertiary syphilis arsenic may be used, but its effects are not so good as in the early stages of the disease, and in my experience it is inferior to bismuth given as iodo-bismuthate of quinine (Fraisse). In tertiary

FIG. 3. FIG. 4.

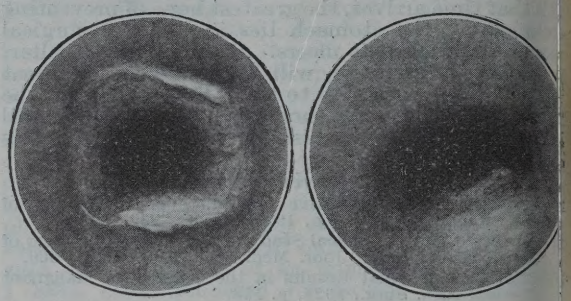

FIG. 3 (Case 1).—Two months later.
FIG. 4 (Case 1).—Eleven months later. (Since then no abnormality has been seen on œsophagoscopy.)

and congenital lesions I strongly advise continuing injections of bismuth for at least four years, with four weeks' rest after each two months' injections; alternate courses of injections may consist of bismuth for one course, mercury for the next, and so on.

Œsophageal Treatment.

Every healed and healing gumma of the œsophagus is accompanied by fibrosis and contraction; therefore the œsophagus must be subjected to frequent dilatations during the early months of the treatment, but later this need only be done at rare intervals, in order to be quite sure that no further active contraction is taking place. In the first instance it should be done under direct vision and, if no contra-indication such as excessive dilatation or diverticulum is present, may subsequently be performed blindly.

FIG. 6.

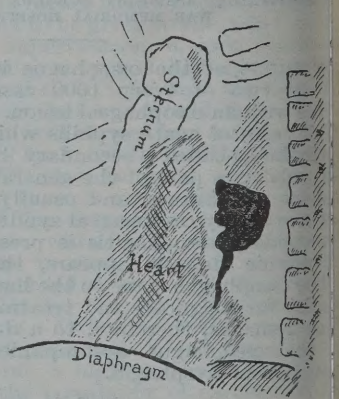

FIG. 6 (Case 2).—Diagram of radiogram of same case as Fig. 5 taken one hour later.

Report of Two Cases of Syphilis of the Œsophagus.

CASE 1. — Female, aged 48. First attended at the Cancer Hospital, London, on June 30th, 1925, under Mr. Percival Cole, who kindly allowed me to undertake her investigation and treatment. This patient first noticed difficulty in swallowing in December, 192 when she began to get occasional attacks of choki after taking solid food, and sometimes brought food that had been swallowed. The symptoms becam progressively worse until September, 1924, when s could only swallow liquid. She said she had be admitted to another hospital where the stricture w dilated. At that time the Wassermann reaction of h blood was positive, and she was given a course of N.A. (novarsenobenzol) injections, after which the Wasserma was negative. She was then free of symptoms until t months before I saw her at the Cancer Hospital, duri which time the dysphagia became progressively worse. admission she could only take very soft solids. Solid fo appeared to stop at the lower part of the neck. There w no history of any previous illness or accident of any kin She had one child, aged 19 years, and no miscarriages.

Physical Examination.—The patient was thin, but n cachectic. She said she had lost a little weight. Colo

l. Complete artificial dentures. Both epitrochlear ds were enlarged, but otherwise there were no clinical s of any abnormality.

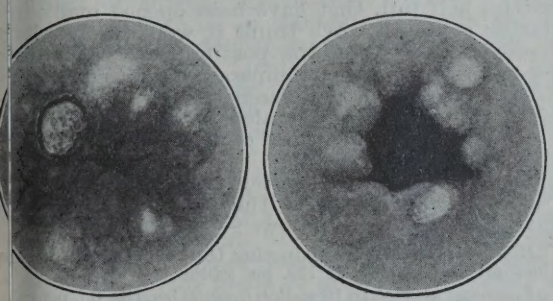
adioscopy, July 2nd, 1925.—Patient could only swallow aspoonful or two of thin bismuth emulsion, which passed slowly from the pharynx into the œsophagus. No other rmality was detected.

sophagoscopy was performed on July 3rd. Immediately nd of the œsophagoscope had passed the cricopharyngeal ncter a dense white fibrous stricture was seen, almost pletely obliterating the lumen of the œsophagus. A patch of leukoplakia was present on the right posterior of the œsophagus at the level of the stricture. A bougie passed and the fibrous constriction seen to split. Three ll bougies were left in situ for one hour. Four days later patient was able to swallow easily. The appearance as by the œsophagoscope before instrumentation is shown ig. 1; as seen a week later in Fig. 2.

ougies were passed, using gradually increasing sizes, y week or two. Fig. 3 shows the condition present in ember, 1925. For the following nine months bougies passed on an average once every two months. The arance on June 7th, 1926, is shown in Fig. 4. Her syphilitic treatment has been carried out on the lines cated above, and is still being continued. A large ie was passed twice in 1927, and met with no obstruc-. The patient has had no difficulty in swallowing since 7th, 1925.

ASE 2.—Male, aged 55. First attended the Cancer pital on July 15th, 1925, and was kindly handed over

FIG. 7. FIG. 8.



7 (Case 2).—Syphilitic stenosis of the œsophagus (thoracic ion as seen by endoscopy.
8 (Case 2).—Two years later.

y care by Mr. Ernest Miles. The patient complained sphagia, which had been gradually increasing for three hs. He brought up solid foods immediately, but fluids retained unless swallowed quickly. He said he ently brought up a great deal of "phlegm." He had losing weight and was a little constipated. He had had ks of vomiting lasting for two or three days every three ur months for six years, and had been treated by his or for "indigestion." He admitted having syphilis ars previously, when he was treated with one bottle of cine only. There was no history of swallowing a sive or foreign body, or of any other serious illness.

examination he was well covered but somewhat anæmic. e was well-marked leukoplakia on the inner aspects of cheeks, with enlarged epitrochlear glands. No other rmality was detected on ordinary physical examination. Wassermann reaction was found to be positive.

ray examination with a bismuth emulsion on July 15th ed an irregular contraction of the œsophagus about inches above the diaphragm, with some dilatation e (Figs. 5 and 6).

sophagoscopy was performed on July 21st, and the arance was as shown in Fig. 7. The stenosis was 13 s from the incisor teeth, and would admit only a very l sound. The mucosa was very red and inflamed, and easily. Patches of leukoplakia were seen on the ned surface with a small area of actual ulceration, which thought to be malignant, and a portion was removed icroscopy. The stenosis was dilated, and a Symonds' left *in situ*. This was vomited two days later. Micro- c examination failed to show the presence of any gnancy, and the patient improved with occasional ation.

o months later œsophagoscopy was again performed, a second portion of the suspected growth removed for y. The appearances were so strongly suspicious of gnancy that two tubes, each of 50 mg. of radium, were *in situ* for six hours by means of an œsophageal catheter. he second microscopic examination was also negative radium was abandoned; antisyphilitic treatment, together with regular dilatation by bougies, was commenced, and the patient improved rapidly. His antisyphilitic treatment has been continued ever since. Bougies were passed at first once a week, then once a fortnight, and then monthly, for nearly two years. The œsophagoscopic appearances as seen on July 14th, 1927, are shown in Fig. 8, and a radiogram taken at the same time is shown in Fig. 9. The patient still has a bougie passed about once every three months, and has no trouble with swallowing unless he gulps very large particles.

FIG. 9.

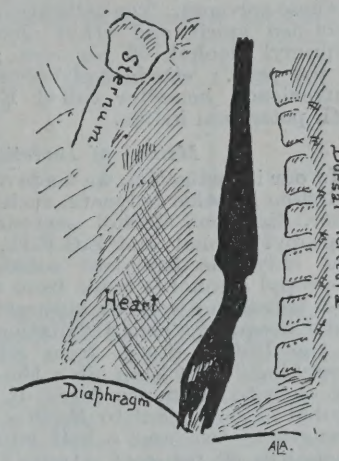


FIG. 9 (Case 2).—Diagram of radiogram of same case as Figs. 5 and 6 taken 18 months later.

The points which I wish to emphasise are: (1) Syphilis of the œsophagus is probably not so rare as a study of the literature would lead one to suspect. (2) Syphilis of the œsophagus is difficult to diagnose by vision alone, either from simple stricture or from a malignant growth. (3) One or more microscopical examinations must be made before pronouncing a case free from malignancy. (4) The patient or his relatives should not be told that he is about to die of cancer when only a specific stricture is present. Conversely, a patient with cancer of the œsophagus should not be given antisyphilitic treatment and energetic bouginage, and told that he will soon be quite normal. (5) Treatment must be by dilatation, as for any simple stricture of the œsophagus, and, in addition, very prolonged antisyphilitic treatment must be undertaken.

SKIN ANTISEPSIS WITH IODINE AND SOME NEW SOLVENTS.

BY R. A. MACDONALD, M.B. EDIN., D.P.H.,
ASSISTANT PATHOLOGIST AND RESEARCH FELLOW, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
J. WICLIFFE PECK, F.C.S., PH.C.,
PHARMACEUTIST TO THE HOSPITAL.

TINCTURE of iodine has long been employed for disinfecting the skin, and its uses as a skin dressing and before operation are almost universal.

Until recently rectified spirit has been the only solvent available as the chemical action of iodine on certain other solvents renders them unsuitable in every way. The extremely irritating vapours produced by the small amounts of methyl alcohol in methylated spirit make this solvent unusable. Methyl alcohol becomes oxidised by the iodine to formaldehyde and formic acid, which attack the eyes and nasal mucous membrane. It is even probable that acetic acid and other products are in course of time formed by the decomposition of ethyl alcohol with iodine, and it has been stated that old tincture of iodine has been known to burn the skin. Rectified spirit bears a very heavy duty, although the Customs and Excise grant a considerable rebate when it is used for medicinal preparations. It is on account of the heavy annual cost to hospitals that we have searched for a solvent that would replace it.

Any new solvent had to comply with the following conditions: (1) It should itself be antiseptic; (2) it should have penetrative powers when applied;

(3) it should not be harmful to the skin; (4) it should be stable; and (5) it should evaporate readily when painted on the skin.

Doubt has recently been expressed amongst surgeons as to whether iodine is an efficient antiseptic, and whether in the solution in general use the more important agent is not the spirit. It seemed advisable therefore to carry out some experiments to find out the actual bactericidal value of iodine in various solvents, as well as considering the relative merits of these solvents. The solvents used were as follows: Rectified spirit and ethyl alcohol, 70 per cent.; isopropyl alcohol, 90 per cent.; isopropyl alcohol, 70 per cent.; ethylene-glycol-mono-ethyl ether (for convenience hereafter called E.G.E.E.) and water with potassium iodide.

Method of Investigation.

In our investigation we made a number of solutions of iodine in other solvents, such as ether, petroleum ether, diacetone alcohol, sextone, sextol, as well as isopropyl alcohol and E.G.E.E., but it was decided that only the last two could possibly be used. Isopropyl alcohol is made from the gases emanating from petroleum wells by absorption in sulphuric acid and subsequent steam distillation. E.G.E.E. is made in the United States from ethylene obtained by "cracking" petroleum oils; the precise method does not seem to be known here. It is stated that ethyl alcohol is germicidal to *Bacillus coli* in 70 per cent. strength in two and a half minutes, and isopropyl alcohol in 30 per cent. strength in the same time. Iodine is said to kill *B. coli* in two and a half minutes in a strength of 1 in 50,000.[1] Ethyl alcohol is more active as a germicide in a strength of 70 per cent. than in any other concentration, being 30 times more powerful than 60 per cent., and 40 times more powerful than 80 per cent.[2] In our investigation the antiseptic properties of the solutions mentioned above were tested as follows: One series of experiments was made in vitro, using cultures of *B. coli* and staphylococci and the other directly on the skin to reproduce as nearly as possible the conditions obtaining at operation.

In vitro.—A measured quantity of each solution was added to an equal quantity of a 24-hour broth culture of each organism, and two drops of the mixture were abstracted by means of a sterile capillary pipette at the end of 1, 2, 3, 4, and 5 minutes. These were at once transferred to tubes containing approximately 3 c.cm. of broth and incubated over night. At the same time controls were put up containing two drops of culture and two drops of the antiseptic added separately. In the case of those solutions containing iodine this was neutralised by adding subsequently some sodium thiosulphate, in order to avoid any inhibition of growth of any organisms not killed by their period in contact with the antiseptic. (It was found later that the organisms grew perfectly in a medium containing two drops of iodine, although this gives a concentration of not less than 1 in 5000.)

On the Skin.—Areas of skin on the front of the forearm were selected, and marked off into segments with a grease pencil. As the majority of the antiseptics used had been found to be lethal to staphylococci and *B. coli* in one minute by the tube test, this period of time only was used. In each case an ordinary sterile throat swab was moistened in sterile broth and then rubbed hard on *part* of the selected area of skin. It was then transferred to a tube of broth and the latter incubated overnight. This served as a control to ensure that there were organisms on that particular piece of skin, before the addition of the antiseptic. The area of skin was then gently swabbed all over with the antiseptic in question. After one minute this area was again rubbed *all over* very thoroughly with a throat swab moistened in broth. The swab was again transferred to a tube of broth and this was incubated overnight. (N.B.—The amount of antiseptic carried over into the broth by this means must have been considerably less than the two drops used in the test-tube controls, and so in this case no further controls were added.)

Results of the Tests.

In the *tube test* growth was present in all the control tubes, but not in any case where one of the solutions had been in contact with the organisms, except ethyl alcohol 70 per cent. with staphylococci, where growth was present in all four tubes, and E.G.E.E. with staphylococci where growth was present in the first three tubes. In the *skin test* growth was present in all the control tubes, and also in all cases where the solvents had been used alone, without iodine. With none of the solutions containing iodine was any growth observed.

Isopropyl alcohol proved to be the most bactericidal of the solvents used, and no trace of irritation was noticed by either of us, after long periods of vigorous swabbing with this fluid. It is said to be twice as toxic as ethyl alcohol, but it is not absorbed to any appreciable extent by the skin or lung. The penetrative powers were tested along with the other solvents as follows:—

Areas of skin on the forearm, which had not been washed for six hours were sectioned off with grease pencil and were painted with the solution of iodine in the solvent in question, using a new camel-hair brush for each area. After the lapse of 30 minutes the forearm was swabbed with cotton-wool soaked in a 5 per cent. watery solution of sodium thiosulphate. The stains from iodine in 70 per cent. alcohol and 70 per cent. isopropyl alcohol were the most difficult to remove, the next being iodine in 90 per cent. alcohol, and the easiest being watery iodine, iodine in E.G.E.E., and iodine in isopropyl alcohol.

We had further to consider whether any decomposition would take place between iodine and the approved solvent. Isopropyl alcohol is $CH_3.CH.OH.CH_3$ and on oxidation yields acetone. We have failed to discover even a trace of acetone in our solutions of iodine in isopropyl alcohol, in bottles half full, that have been opened many times during a month. We think it would be advisable, however, in view of the possibility of oxidation, to recommend the use of comparatively recent solutions. Lastly, there is little difference between the evaporation rate of isopropyl alcohol and that of ethyl alcohol, the boiling point of the former being only 2–3 degrees higher than the latter.[3] Isopropyl alcohol, moreover, has quite a pleasant smell.

The relative costs of the solvents used in this investigation are as follows:—

Rectified spirit, after deducting the rebate allowed by the Customs and Excise, £2 13*s.* per gallon.

Isopropyl alcohol, in 10-gallon quantities, 13*s.* 6*d.* per gallon.

E.G.E.E., in 10-gallon quantities, 11*s.* 6*d.* per gallon.

Isopropyl alcohol 70 per cent. would be approximately 10*s.* 6*d.* per gallon, and if used generally in hospital would produce a saving of about 85 per cent.

Conclusions.

Our conclusions, therefore, are: (1) that iodine in the strength of 1·25 per cent. is in itself an efficient antiseptic; (2) that isopropyl alcohol is the most antiseptic of the solvents used in this experiment; (3) that iodine 1·25 per cent. in isopropyl alcohol is not harmful to the skin; (4) that its penetrative powers and evaporation rate are equal to those of ethyl alcohol; and (5) that its cost is very much less than that of rectified spirit. We therefore strongly recommend iodine 1·25 per cent. in 70 per cent. isopropyl alcohol as a substitute for the commonly used iodine in rectified spirit.

We wish to thank Dr. D. N. Nabarro, director of the pathological department, for permission to carry out this work, and for his kind interest and assistance.

THE RATING OF HOSPITALS.—The County Valuation Committee for Cornwall has decided to assess hospitals at a uniform rate of 7*s.* 6*d.* per bed, but the Truro Rural Rating Committee has resolved not to demand rates from hospitals and similar institutions.

NEW HOSPITALS FOR EGYPT.—The Egyptian Government has adopted a scheme for the provision, at a cost of £1,500,000, of 100 hospitals in various towns and villages, to be completed within the next five years. The institutions will be open to all classes of the population, especially to the fellaheen, who will thus no longer be compelled to travel long distances to the nearest hospital.

Clinical and Laboratory Notes.

A NOTE ON THE SO-CALLED WHITE LINE OF ADRENAL INSUFFICIENCY.

A. MUIR CRAWFORD, M.D., F.R.F.P.S. GLASG.,
ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY.

In certain individuals, if the skin is lightly stroked h the pad of the finger or the smooth rounded l of a fountain pen, a band of pallor is produced the area of skin corresponding to the part stimued. This phenomenon was closely studied by gent,[1] who regarded it as a valuable clinical t. He considered it to be pathognomonic of enal insufficiency and termed it "the white line adrenal insufficiency" (*la ligne blanche surrénale*). nsiderable interest has been shown in the reaction, tably among French clinicians, and reference to subject is to be found frequently in French rature. In this country and in America, several rkers have investigated the reactions produced cutaneous stimulation, with results which apparly show that the reaction is of no clinical value a sign of adrenal insufficiency. Thus, Cotton, de, and Lewis,[2] in an elaborate investigation on phenomena of dermatographism carried out on diers affected with "irritable heart," refer to the narkably sharp outline of a white band produced stroking the skin with the end of a flat ruler in a ceptible subject. Their observations were made h special reference to the effects of pressure of a nt point drawn firmly over the skin. This ariably demonstrated the appearance of a red he of varying intensity, with or without borders distinct pallor, and they concluded that the riations in the type of reaction could be attributed differences in the grade of pressure. In many of ir cases light pressure produced a simple white e, whereas, in other cases, light pressure was her without effect or produced a transitory red id. Wright,[3] working in the Physiological Departnt of the Middlesex Hospital Medical School, investigated the significance and value of gent's white line by applying the test to healthy jects. He carried out the test on 100 young dical students and in each case recorded the tolic and diastolic blood pressures. A positive ult was obtained in 66 per cent. of the tests, and observations led him to the conclusion that the ite line of Sergent is a phenomenon occurring in arge proportion of normal subjects, that it is not uted to adrenal insufficiency or to abnormally systolic or diastolic blood pressure, and is, in t, without pathological significance.

Personal Observations.

n order to test further the value of the phenomenon hought it might be of interest to carry out the on hospital patients of different ages and affected h different types of disease. Tests were, therefore, carried out on 100 ward patients in the Glasgow yal Infirmary. The patients were affected with usual diseases seen in a general medical ward, no selection was made of either patient or type disease. The test was carried out by lightly oking the skin of the anterior abdominal wall h the smooth rounded end of a fountain pen, due ention being paid to the details of the Sergent nique. After a few preliminary observations it decided to record the results as follows:—

Negative, where there was either no result or where stroking was followed by a red line.

Positive +, where there appeared a definite but not ked band of pallor.

Positive ++, where there appeared a very marked te band with clear-cut edges.

This method of recording the results is very similar to that employed by Wright. Although accurate time observations were not made, it was generally found that a positive reaction appeared in about 20 to 30 seconds and lasted for one to two minutes. The following tables show the results obtained. Of 100 cases examined, 49 per cent. gave a positive reaction (14 per cent. were positive ++, and 35 per cent. positive +), while 51 per cent. were negative.

TABLE I.—*Showing Results in Relation to Age and Sex.*

Age in years.	Sex.	P.++	P.+	N.
10 to 20 ..	M.	0	5	3
	F.	3	6	4
21 to 35 ..	M.	6	7	3
	F.	2	8	3
36 to 50 ..	M.	1	3	12
	F.	2	2	4
Over 50 ..	M.	0	4	16
	F.	0	0	6

P. = Positive. N. = Negative.

An examination of Table I. shows that a positive reaction was obtained far more frequently under 35 years of age than over. This is in accordance with the results obtained by other observers. Thus, Kay and Brock [4] state that the white line occurs most frequently in young adults of either sex. In my series, in 29 patients between the ages of 21 and 35 years, 79·3 per cent. gave a positive reaction, while in 50 patients between the ages of 36 and 74 years, only 24 per cent. were positive.

TABLE II.—*Showing Results in Relation to Type of Disease.*

Disease.	P.++	P.+	N.	Disease.	P.++	P.+	N.
Gastro-intestinal	1	9	14	Diabetes m. ..	1	3	2
Respiratory ..	2	7	15	Blood	0	0	4
Exophthalmic goitre	4	0	1	Renal	2	5	4
Rheumatic ..	0	2	2	Cardiac	2	4	3
				Nervous ..	2	4	3
				Miscellaneous	0	1	3

Diabetes m. = Diabetes mellitus.

The only criticism I have to offer on these results given in Table II. is that in four cases of exophthalmic goitre the reaction was obtained in a very marked degree; in fact, they showed a white band more intense than that obtained in any other disease. This tends to support the hypothesis formulated by Tracy [5] that the white line is a manifestation of sympatheticotonia.

TABLE III.—*Showing Results in Relation to Blood Pressure.*

—	P.++	P.+	N.
Average systolic pressure ..	119	117	122
Average diastolic pressure ..	69	72	73
Average pulse pressure	50	45	49

A glance at Table III. shows that no definite relationship can be demonstrated between blood pressure or pulse pressure and type of reaction.

Conclusions.

As a result of these observations and from the reports published by other investigators it would appear that (1) the white line of Sergent is a phenomenon which may be readily demonstrated in a large percentage of young adults; (2) it bears no relationship to the sex of the individual; (3) it bears no relationship to the blood pressure and is not pathognomonic of adrenal insufficiency; (4) it bears no relationship to any particular type of disease, although

sometimes it may be specially marked in certain pathological states not connected with adrenal insufficiency.

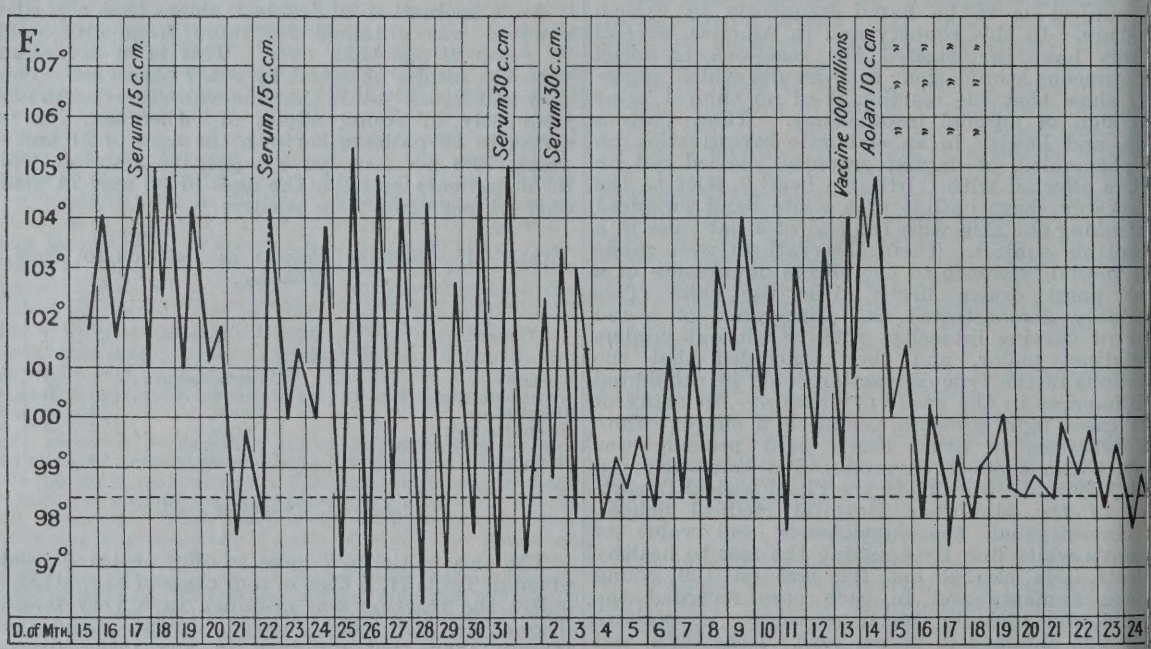
NON-SPECIFIC PROTEIN THERAPY IN ERYSIPELAS.

BY HENRY C. SEMON, M.D. OXF., M.R.C.P. LOND.,
PHYSICIAN, DISEASES OF THE SKIN, ROYAL NORTHERN HOSPITAL.

THE respective potencies of specific as opposed to non-specific protein therapy, both of acute and chronic infections, are still sub judice, and the injection of a stock vaccine on June 13th appears to been followed by an even higher temperature, almost

The patient was very ill indeed when I was asked t her in consultation on June 14th, the thirty-first day o infection. She had a running pulse of 130, a temper of 105°, and was almost comatose. It was very dif to rouse her, and there was complete loss of control o sphincters. The erythematous rash on the scalp and was slightly œdematous in places, but had not the ty sharply defined raised edge of text-book descript Nevertheless, the rest of the picture left no doubt of the n of her infection. My first suggestion, to give an intrave injection of gr. 1/16 of perchloride of mercury, was op by one of the consultants on the ground that she had n stenosis and probably some valvular vegetations, w he believed he had seen detached by this procedu another case. No objections were raised to the intramus injection of 10 c.cm. of aolan, a germ- and toxin-free de tive of cow's milk, which is put up in 5 and 10 c.cm. amp by the firm of Beiersdorf, in Hamburg. The injection made into the buttocks, 5 c.cm. intramuscularly, and an 5 c.cm. into the fascial planes over the glutei. No har effects were observed at the time, and that same eve the temperature fell to 101°. 10 c.cm. were given o three following days, and 5 c.cm. on June 17th and The effects on the temperature are well illustrated by



Temperature chart of a case of erysipelas, showing improvement under the influence of aolan.

adherents of the former doctrine could doubtless produce examples in support of their contentions as striking as the one here submitted. The writer holds no fixed views in the controversy; his object is merely to call attention to a very harmless and sometimes exceedingly effective means of stimulating to their utmost capacity the natural protective mechanisms against disease.

A middle-aged married lady had suffered from an aural furunculosis for about three months. On May 15th last, on her return from the seaside, she appeared to have caught a chill, and on the following day at noon she went to bed with a temperature of 102° F. She complained of deafness and a feeling of fullness over the right ear and cheek. On the 17th an erysipelatous eruption appeared in those situations, and during the course of her illness in the following weeks wandered over the scalp and the rest of the face in an irregular manner. Each extension appears to have been associated with rigors and increase in the temperature.

An injection of antistreptococcal serum was given on May 17th, but there was no fall in temperature until May 21st. A second injection, given on the following day, appeared to have some effect, but doubled doses on the third and fourth days produced no result. Two attempts to grow the organisms from the blood were unsuccessful, and the chart, and the improvement in the general condition ceeded pari passu with the fall of temperature. The eru on the scalp and forehead did not appear to be influe to the same extent, but this was at no time a very str feature of the case, and gradually involuted under applications of a weak solution of ichthyol and lead.

The recovery was so striking that the case s worthy of record.

A NEW CULTURE MEDIUM.

BY C. Y. WANG, M.D., F.R.C.P. EDIN.

(From the School of Pathology, University of Hong-Kon

THE following preparation is the outcome series of experiments I have had occasion to con whilst studying certain aspects of the biolo properties of bacteria, for the purpose of raising e and abundant growth :—

Trypsinised defibrinated ox blood	10 par
,, plain bouillon	8 ,,
,, plain milk medium	4 ,,
Beaten whole egg	10 ,,

Preparation of the Medium.

ıe defibrinated blood should be fresh, but need not be ined with aseptic precautions. For trypsinisation, to 7 10 c.cm. of blood add 0·2 c.cm. of liquor pancreaticus ger's). The treated blood is left overnight (18–24 hours) ° C., but should be occasionally shaken during the first hours of incubation. The bouillon is the ordinary one broth made with meat extract and adjusted to the l reaction. Trypsinisation is effected by adding c.cm. of liquor pancreaticus to every 8 c.cm. of broth, ng to stand overnight at body temperature. Strict ic precautions are to be observed in this procedure, e end of which the broth should remain clear. The milk um is similarly prepared and should show practically hange in reaction. After being trypsinised the three s are well mixed with the beaten egg, and the whole ure is strained through gauze or muslin and distributed bes. These are sloped in an inspissator, so heated as to 3½–4 hours to reach 75° C., at which temperature they in for 15–30 minutes before being autoclaved at C. for 20 minutes.

Growth of Various Organisms.

n this medium the growth of the tubercle bacillus apid at body heat. In subculture the minute nies, somewhat raised above the surface and nly visible to the naked eye, soon become con- ıt and nodular in appearance. Examined micro- ically the organisms present marked pleo- phism, some appearing as beaded bodies 15–20 μ ength, a few of them so disposed as to give the earance of a chain of streptococci. Here and e, at one or both ends of the organism, detached ls appear as minute cocci. Other organisms are as irregularly disposed rounded bodies, as small *B. melitensis*.

he pneumococcus grows very rapidly on the ium. When sown from a loopful of a thin emul- , scarcely turbid to the naked eye, it yields in 16 hours an abundant growth of colonies which in 36 hours become flattened out, appearing as sy patches. The organism tends to retain its ility for many weeks, if evaporation is prevented. growth far surpasses that obtained on other ia, such as blood-agar or solidified serum.

he streptococcus thrives extremely well. Unlike e of the pneumococcus, the colonies do not tend atten out.

he diphtheria bacillus develops readily; at 24 hours after incubation the colonies are more ierous than those seen on Löffler's serum.

he medium has also been found favourable for growth of other bacteria, such as the meningo- us, hæmophilic bacilli, and the organisms of ders and plague.

OYAL NATIONAL ORTHOPÆDIC HOSPITAL.—The al report states that the new buildings at the country ch at Brockley Hill, Stanmore, are now occupied and ide 90 additional beds, with an operating theatre other accommodation. There are now 214 beds at more, and the King's Fund has promised a further 0 towards the provision of another 50 beds there. additional 70 acres of land have been purchased h will not only provide for future extensions, but ensure the maintenance of the rural character of ospital.

LORENCE NIGHTINGALE FUND.—The annual report ıe Florence Nightingale Fund School at St. Thomas's ital states that last year there were 156 probationer s under training. Of these, 70 were taken on extra nurses to complete their training, 37 com- d their term and received certificates, and only resigned or were discharged as unsuitable. The was raised after the Crimean war in recognition Miss Nightingale's services and has an income of 0 a year. It claims to give the best training a e can receive, and, owing to the demands upon the for important outside posts, the matron has been elled for the moment to refuse to allow further s to be made upon it.

Medical Societies.

ROYAL INSTITUTE OF PUBLIC HEALTH.

DUBLIN CONGRESS, AUGUST 14TH–20TH, 1928.

MEMBERS were received at the Mansion House by the President, General R. Mulcahy, Minister for Local Government and Public Health, President Cosgrave being among the hosts. At the inaugural meeting a further welcome was given by Mr. Seamus Murphy, the Chief Commissioner of Dublin, who was supported by the Vice-Provost of Trinity College, the President of the National University College, Dublin, and the Presidents of the Royal College of Physicians, the Royal College of Surgeons, and the Apothecaries' Hall, Ireland. General Mulcahy, in his opening address, referred to the problems in front of the Free State, remarking that they were watching with interest the results of the English inquiry into maternal mortality. He also acknowledged the generosity of the Rockefeller Foundation in aiding the establishment of efficient county public health services. General Mulcahy was presented with the Honorary Fellowship of the Institute by Sir Thomas Oliver, and the opening session terminated with greetings from many overseas delegates.

SECTION OF BACTERIOLOGY, PATHOLOGY, AND BIOCHEMISTRY.

Prof. JAMES M. BEATTIE gave a presidential address entitled Public Authorities and Research, which was printed in THE LANCET last week (pp. 430–31).

Prof. W. D. O'KELLY (University College, Dublin), who followed, while agreeing in general with Prof. Beattie, thought the problem was how to convince the local authorities that this was going to be an economic proposition.

Prof. J. W. BIGGER (Trinity College, Dublin) had something to say in favour of institute research, for the individual was able to consult at any stage with experts in other lines. Further, he himself favoured pure research and did not think Dr. Beattie distinguished sufficiently between research and investigation. It would be difficult in Ireland, he thought, to persuade the local authorities to spend money on research. Dr. Bigger went on to read a paper entitled the Expectation of Life and the Bacteriological Laboratory (which also led up to the question of the endowment of research). He compared the deaths in Ireland from 20 groups of diseases in 1875 and 1925 respectively. He showed that in 15 groups there had been a fall in the death-rate and in 5 a rise. In 13 of the 15 cases the falls were in bacteriological diseases, whereas in only 1 of the 5 "rises" was the disease a bacterial one. Bacteriology had saved very many lives and would in time save very many more. In Ireland, however, the public health authorities had not even applied the incomplete knowledge which we possessed at present. Ireland lagged behind in the provision of laboratory facilities for diagnosis and for the detection of carriers, and had made no use of recent advances in diphtheria and scarlet fever.

Dr. NORAH H. SCHUSTER (pathologist, Royal Chest Hospital, London) read a paper on primary carcinoma of the lung. She produced evidence that there was a real increase in this disease in London and stated that a similar increase had occurred in various foreign cities.—Dr. BEATTIE pointed out that in a large experience he had never seen this disease associated with the pneumoconioses of the Sheffield grinder.—Prof. W. BOXWELL (Dublin) stated that primary carcinoma of the lung was very rare in Dublin.—Prof. J. T. WIGHAM (Dublin) suggested that an investigation as to why this disease was rare in one place and increasingly prevalent in another might lead to interesting results.

In another paper Dr. BIGGER dealt with the bacteriological control of shell-fish, describing a method adopted by him for determining the fitness of shell-fish for human consumption, which was essentially a modification of Klein's. He referred to the discordance between the results obtained by him acting for the Department of Fisheries and those obtained by Prof. J. W. Eyre for the Fishmongers' Company. He believed that the divergent results were chiefly due to chance in the selection of shell-fish and chance in the selection of the particular fraction of shell-fish fluid examined. He thought his own method gave more reliable and just as rapid results as the Houston-Eyre method.—The desirability of the adoption of a uniform standard was brought out by the discussion.

Dr. GEOFFREY BEWLEY (Adelaide Hospital, Dublin), in a paper on the Schick test, showed that the mortality from diphtheria had always been smaller in Ireland than in England and Scotland. The rates in England and Scotland, however, had recently been greatly reduced, whilst that in the Free State had been practically stationary. The number of Schick reactors was probably proportionately greater in the Free State than in England. In the Adelaide Hospital 54 per cent. of the nurses were positive, as compared with an average figure of 25 per cent. for English hospitals. From this he inferred that the soil was prepared, and that diphtheria might at any time assume epidemic proportions in the Free State. The prophylactic inoculation of the children was, therefore, worthy of consideration.

Prof. BLAIR BELL (Liverpool) claimed that the clinical results of combination of the lead and X ray therapy for cancer is better than those obtained from either alone. He reviewed their 1925 statistics in the light of subsequent history. Of 31 cases which were believed to be cured 3 had since died, 2 from intercurrent disease, and 1 from recurrence. The remainder were alive and healthy.—Dr. LESLIE CUNNINGHAM described the toxic effects of intravenous lead and emphasised the need for careful study of the variation in functions of the liver during the treatment.

SECTION OF CHILD WELFARE.

Prof. A. LOUISE MCILROY (London), in her presidential address on the Progress of Midwifery in the Present Century, referred to Dublin as the Mecca of obstetrics. Bedside teaching in the three great hospitals was given by experts. There had been much advance in antenatal work between 1900 and 1925. Obstetrics, once the Cinderella of medicine, raised to a science, would promote the dignity of motherhood and the saving of child life. She referred gratefully to the pioneer work of Ballantyne, of Edinburgh, and proceeded to deal with changes wrought by antenatal supervision. Disease in expectant mothers was now treated as disease complicated by pregnancy rather than pregnancy complicated by disease. Wonderful results had accrued from the work of a special heart clinic for pregnant women at the Royal Free Hospital. Rational treatment had been introduced for eclampsia to take the place of induction of labour and high forceps cases with their great mortality. To this change Dr. Hastings Tweedie, of Dublin, had contributed much. Research had been promoted as to the normal and the abnormal. Decayed teeth might give rise to eclampsia and toxic symptoms, therefore the work of a dental clinic for expectant mothers was extremely important. X ray examination was invaluable for removing doubt as to pregnancy, &c., though some might question the advantage to the mother of learning a few months beforehand of the advent of triplets, against which risk insurance companies had now refused to insure. Practice was taking the place of lectures in the teaching of medical students. There should be, now, few emergencies in homes unsuitable for complicated labour. The spreading of this knowledge would help the cause of better housing and the demand for more skilled attention for mothers. Hurried lab should become a thing of the past. She had fo gas and oxygen the ideal anæsthetic for labour in reply to a question, mentioned that a port apparatus for the purpose was being worked with promise of success. Although there wa yet little improvement in sepsis mortality, s morbidity was becoming less. For sepsis she glycerine drainage with vaccines and open-air t ment. Hopeful research as to vaccines was in pro based on the Dick tests. She believed in se rather than autogenous vaccine. Since the drai of the uterus by glycerine had been introdu the douching of the uterus and vagina had discarded, but in certain cases intestinal lavage good. The treatment of venereal disease in p nancy prevented the birth of syphilitic babies gonorrhœal ophthalmia. Through postnatal cl and preventive midwifery they would ultima have more maternity and fewer gynæcological t as 50 per cent. of the gynæcological beds wer present filled by conditions due to bad or meddles midwifery. The sacrifice of the child by induc of labour was very seldom necessary. Hyperem and retroversion of the gravid uterus ought not t as formerly, common causes of abortion. In seven a half years in the Royal Free Hospital they had no case of craniotomy, owing to improved Cæsa technique or antenatal work. Subsequent no labour might occur after Cæsarean section with scar still holding. The same antenatal care good for both mother and child. Considering aims, obstetrics was the greatest subject in medi and the new teaching must be spread to the Connen mothers.

The claims made by Dr. McIlroy for antenatal t ment received ample confirmation in later paper Dr. LOUIS CASSIDY (Master, Coombe Hospital) poi out that 30 per cent. of pregnant women ne much care throughout pregnancy. Early abor was preventable. In seven years at the Coo they had only had two deaths from pernic vomiting and both these cases were moribund admission. By early treatment with rest in bed a suitable vitamin-rich diet much could be d to avert fœtal death and trouble from kidney dise Contraction of the pelvis was becoming rarer. In prevention of autogenous sepsis attention to se teeth, the nasopharynx, and the bladder important. There should be no vaginal examina in normal cases. For the education of the med student three months' residence in a mater hospital should be required. Obstetricians sh make a more determined effort to secure repre tation on the General Medical Council. Preven midwifery would abolish craniotomies and n Cæsarean sections comparatively rare. Women n be persuaded to go early to the antenatal clinic

Dr. N. FALKINER mentioned that at the Rotu breech presentations were only rectified if this c be done easily by external versions. They had living babies in all their last breech deliveri Dr. A. W. SPAIN (National Maternity Hospital) sidered that there were good antenatal facilities the poor and, he believed, the rich also availed th selves of antenatal advice, but the middle class not. They must educate the public through medical officers of health.—Dr. BETHEL SOLOM (Rotunda) thought that antenatal clinics should be held at maternity hospitals. Every woman sh have antenatal care and the private practition fee should include this. He criticised severely rule of the Central Midwives Board making vag examinations by midwives compulsory. The rec cation of breech presentations might result in death of the baby by the twisting of the cord give rise to the separation of the placenta. believed that the results obtained in the mater hospitals of Scandinavia and Dublin were the in the world.—Dr. G. W. FITZGERALD (Manches advocated that part of the improved training

medical student should be post-graduate. He hasised the fact that the theory of autogenous tion was a dangerous doctrine. Other points e were that antenatal clinics, if not always held naternity hospitals, should at any rate be con- ed by experts, and that, if possible, the confine- ts should be conducted by those who had done antenatal examinations.

he discussion brought out the fact that two-thirds he births in Dublin were attended through the rn and extern departments of the three hospitals, a resolution was passed requesting the masters onsider the preparation of statistics on a con- rable scale which would establish the value of natal work.

School Medical Service.

r. J. A. HARBISON (Kildare), after describing aim of preventive medicine as medical "super- on from conception to corruption," went on to v what gaps needed to be filled. They wanted ery schools like the McMillan to teach habits to toddler, and they wanted health education for r scholars.—Dr. T. S. FULTON (Belfast) emphasised unhygienic condition of many of the schools. In ast they had much leeway to make up. Out 86 schools only seven were really good. They were avouring to renovate five every year at a cost bout £30,000, and expenditure on nursery schools at present starved out in Belfast, though the need them was recognised.—Both speakers deprecated ied examinations and the undue importance ibuted to statistics. The need for the education he public and of education authorities in the difference between a nursery school and the nary infants' department of an elementary school emphasised in the discussion.

r. A. DINGWALL FORDYCE described the beginning le in Liverpool in the supervision of the rheumatic ol-child by means of a hospital clinic coöperating the public medical services. Many more dential beds and convalescent homes were needed Merseyside for this work. Head-teachers should ully notified how to deal with each rheumatic l.—Dr. CATHERINE CHISHOLM (Manchester) from experience said that rheumatic febrile attacks in 1–5 age period could be discovered if sought for.—LETITIA FAIRFIELD described the scheme for matic children carried out by the coöperation of 's Hospital. They had special classes in the ysically defective" schools for such cases and ht them a suitable trade from 12 years old ards. An important point made in the dis- ion was that school medical officers, like tuber- sis officers, should be in some way attached to pitals and thus given a wider clinical field. Dr. field gave an extremely interesting account of working of the L.C.C. scheme for mentally ctive children, and in replying to a vigorous ussion she said there had been no dull and ward in the London M.D. schools during the ten years. She further said that mongols were itted to the M.D. schools, but that their education a waste of money. She wished something could lone to correct the impression that thyroid was ficial to mongols, as absolutely fallacious hopes aroused in parents. Modern opinion was dead nst sterilisation. Those for whom sterilisation justifiable also needed confinement.

OTHER SECTIONS.

me 80 contributions, a large proportion of which from representatives of the Free State, official non-official, were discussed at the five sections their various subsections.

of. P. ABERCROMBIE (Liverpool) dealt with town rural planning, and referred to the modern anti- l phenomenon of "ribbon" building. He advo- d instead the grouping of houses on side roads ight-angles to the main artery, so as to secure pact communities.—Mr. J. WEBB (President of the Royal Institute of Architects of Ireland) pressed the urgency of planning for all the towns and rural areas of Ireland.—Mr. GEORGE BECKETT (Vice-President R.I.A.I.) said his institute has been pressing the Government during the last five years for planning measures. He believed that the city commissioners were quite alive to the importance of planning but that the Government was not.—Dr. W. C. DWYER (one of the three Dublin commissioners) pointed out the urgent need for town planning in Dublin, and emphasised the disastrous effect of bad housing on education.—Mr. MANNING ROBERTSON, M.R.I.A.I., said that Ireland lagged hopelessly behind the Continent in town and regional planning, and that a comprehensive planning Act was needed. Fortunately for Ireland, he said, they had not inherited the legacy from uncontrolled industrialism that was the despair of England's housing reformers. He moved a resolution, which was accepted by the section, recommending the Government to set up a planning commission for the development of the Free State as a whole.—Mr. W. J. BYRNE (Dublin Commercial Utility Society) showed how much could be done by utility societies if the local authorities throughout the Free State would grant to them the facilities provided for under the various housing acts.—Mr. H. T. O'ROURKE (city architect) outlined the activities of the Dublin Corporation. Modern methods of dealing with the housing problem in the congested areas of old towns were so hopelessly uneconomic that he had practically reached the conclusion that free housing was as necessary as free education.—It was clear from the discussion that the spoiling of the country-side, although it had not reached so advanced a stage as in England, was quite sufficient of a menace in the Free State to provoke vigorous protests. In order to deal with this menace Mr. R. M. BUTLER (Professor of Architecture, University College, Dublin) urged that "committees of taste," composed of architects, artists, road engineers, and business men should be set up in every district.

Dr. GERALD LEIGHTON (Scottish Board of Health) advocated a great extension of the fixing of standards for foodstuffs.—Mr. J. H. NORRIS (Director of Veterinary Research) estimated that 20 per cent. of the Irish dairy cattle were tuberculous and strongly supported the recommendations of the Free State Inter-departmental Committee, which included veterinary inspection of dairy cattle, the extension of the tuberculosis order, and the grading of milk.—That the Free State will be able to profit by our experience and secure a better nomenclature for graded milks was pointed out by Mr. J. MCALLAN (Chief Veterinary Inspector, Aberdeen).—A joint contribution from Dr. E. G. GIBB-SMITH (M.O.H., Teddington) and Dr. F. HOBDAY (Principal, Royal Veterinary College) drew attention to the unsatisfactory form of bottle used for milk and to its inefficient capping. The authors also suggested the possibility of destructible containers for milk.

Dr. P. C. VARRIER-JONES, in his presidential address, referred to the failure of sanatoriums to cure tuberculosis. Sanatorium treatment only touched the fringe of the matter. The crux of the question was the provision of suitable employment under sheltered conditions with facilities for treatment when required. Village settlements, such as Papworth, fulfilled these requirements.

A TUNBRIDGE WELLS CENTENARY.—The centenary of the Tunbridge Wells General Hospital was observed during the week ended August 18th, when funds were raised towards the £100,000 needed for the building of a new hospital at Great Culverden, Mount Ephraim. In 1926 the governors agreed to mark the centenary by beginning the erection of a new building, instead of spending many thousands of pounds in extensions. The new hospital, which will have 150 beds, will combine the eye and ear hospital, now in its fiftieth year, and a considerable portion of the £100,000 needed will accrue from the sale of the two sites. Building is to be started in a few months.

Reviews and Notices of Books.

From Magic to Science.

By Charles Singer, M.D., D.Litt. Oxf., F.R.C.P. Lond. London: Ernest Benn, Ltd. 1928. Pp. 253. 25s.

These essays deal with what their author terms poetically "the scientific twilight," and have all been printed at various times during the last ten years. But as they are scattered through various publications, some of which are not easily accessible, and as they represent a continuous development of a single line of thought, Dr. Singer has been well advised to bring them together with such modifications from the original form as later publication warranted. We have thus set out what may be called the story of early accomplishment in natural philosophy, as human knowledge groped its way from myth to something of exactitude.

The first essay briefly describes science under the Roman Empire. The author shows the superficial nature of the resemblance of the Lucretian theory to modern atomic views, and gives proper credit to Pliny and Seneca as the two founts of ancient Roman learning whose written works were not lost during the dark ages. Pliny's credulity, however, in medical matters deserves the exposure which it receives. The position of Celsus is accurately described, with much interesting information on the Roman hospital system and the growth of hygienic ideas from prehistoric times. The "Dawn of Science," the subject of the second essay, receives no particular date, but Dr. Singer suggests that we may fix the end of Antiquity and the beginning of the Middle Ages for science at the end of the fourth or the beginning of the fifth century. The lowest degradation of the human intellect in Europe generally may be placed in the tenth century, after which a slow ascent can be discerned. By the thirteenth and fourteenth centuries there is considerable expansion of natural knowledge, and Dr. Singer places the limiting date of the mediaeval attitude towards nature as 1543, and gives his reasons in great detail, which should be read in connexion with an informing chronological pedigree of mediaeval science. Three hundred years earlier the first truly scientific wave which our comparatively modern world experienced marked the arrival of Roger Bacon, while it need hardly be said that Leonardo da Vinci, Paracelsus, and Vesalius are in the pedigree, the last named being contemporary with the critical year. A chapter on the Lorica of Gildas the Briton introduces a subject of medical interest which will be novel to most readers. The lorica was literally a coat of mail, but the word was used for religious spells or invocations of a protective character. The most famous of the loricæ was that attributed to St. Gildas, which is Celtic in character and of date about 600—there is doubt about the exact period. It appeals to the Trinity and to the Hosts of Heaven in 47 stanzas which form a catalogue of the various parts of the body, and lest the compiler should have omitted any part he asks that other members of the body should be held to cover the names of which he has perchance left out. As the chief interest in the Lorica of Gildas is the extraordinary vocabulary of foreign words, the origin of many of which are obscure, Dr. Singer adds very full notes on them which, as he explains, give an idea of how, at certain cultural stages, any phrase or idea that is foreign or strange can be enlisted by the magician for his purposes. An appendix to the chapter describes the six known manuscripts of the Lorica of Gildas, one of which is in the British Museum and forms mainly the text for the essay. In the last essay, which deals with some of the legends which gathered round the school of Salerno, Dr. Singer questions the suggestion that that centre of learning gave free access to women, and states how one of its alleged female celebrities, Trotula, was other than a man—one Trottus—and that Tr passed long ago into the fairy tales as Dame Thus fades into nothingness, he says, the first w professor whose life a learned medical hist Salvatore De Renzi, once essayed to write i Collectio Salernitana.

We have to thank Dr. Singer for a learned, am and suggestive book, and one of special intere medical men inasmuch as from our science m the examples of evolutionary knowledge are t The illustrations are an interesting feature o volume.

Some Principles of Diagnosis, Prognosis Treatment.

A Trilogy. By Robert Hutchison, F.R.C.P., Physician to the London Hos Bristol: John Wright and Sons, Ltd. 1928. P 2s. 6d.

Whenever Dr. Robert Hutchison gives an ad his audience may expect something interesting, and sound. This little book could be bought read with profit by every specialist and ge practitioner, young and old, in the land. I specialist Dr. Hutchison's broad outlook should to preserve a mental balance which is sometim danger; to the young general practitioner practical principles he lays down are invalu while the older man will chuckle as he sees Hutchison put into pithy sentences the conclu which he has himself arrived at by experience bu been unable to formulate. The book contains addresses, two of which are reprinted from w medical journals, while the third is taken the author's book on "The Elements of Me Treatment."

In his preface Dr. Hutchison says that his o is to repeat and emphasise the elementary prin of diagnosis, prognosis, and treatment, which a danger of being ignored through the rapid adv of modern medicine on the laboratory side. not that Dr. Hutchison despises modern methods he is anxious to show that medicine is and remain an art, and that our duty is not finished we have put an appropriate label on the sympt In diagnosis the author comments on the faculties which are called into play—observa knowledge, and judgment, and gives a list of "do Prognosis he characterises as the branch of med which has, perhaps, made least progress since time of Hippocrates, and he discusses most admi the vexed question of "What the patient shou told." Treatment is discussed under appro headings, and Dr. Hutchison emphasises the im ance of paying attention to the patient's likes dislikes, quoting Sydenham to the effect that " importance is to be attached to the desires feeling of the patient, provided that they are excessive or dangerous, than to doubtful and falla rules of medical art."

Childbirth.

By William George Lee, A.B., M.D. Unive of Chicago Press. 1928. Pp. 300. 15s.

The manuscript of this book was completed before the death of the author. It consists o personal views of a leading American obstetr not only on the theory and practice of obste but also on what he considers to be the ideal me of organising the maternity service of a cou Some of his ideas on organisation are excel others will receive little sympathy in this cou The following passage is hardly likely to repr current American or British opinion. "The mi still persists to-day as an evolutionary remna our midst, although, like the vermiform appe she is now of concern chiefly because of the amount of harm she originates, her essential funct

ring long since been lost." The author possesses power of explaining difficult points in the simplest guage. Only 50 pages are devoted to normal our, but the whole process could be readily under- od by an intelligent lay reader; yet few experi- ed obstetricians would fail to derive benefit from ding the account. A long and careful survey is en of the reasons for interfering with the course labour; under this heading are grouped such ious conditions as hæmorrhage, contracted pelvis, malpresentations. This is a mistake from the dent's point of view, since the characteristic ures of each of these abnormalities are not clearly out. The procedures recommended are in the n orthodox, but the author's recommendation of rine tamponade as a routine after manual removal the placenta is unusual. Dr. Lee gives a full ount of the Kjelland forceps; he considers this rument the best for general purposes.

he book will be of interest mainly to those who ady have a fair amount of experience in obstetrics.

STRO-INTESTINAL DISEASES.

Lectures delivered at the James Mackenzie Institute for Clinical Research. London: Humphrey Milford, Oxford University Press. 1928. Pp. 278. 10*s.* 6*d.*

HE collection of articles which form this volume sists of lectures delivered at the James Mackenzie titute at St. Andrews during the winter session of 7. Containing as it does the views of 11 eminent tish authorities, together with discussion of their nion by no less eminent critics, the volume is re than readable; it becomes practically a treatise many unusual problems in connexion with the nentary canal. We would call attention partiarly to the article by Dr. E. Matthew on hæmaesis, and that by Prof. D. P. D. Wilkie on gallder disease as being models of what advanced ures should be. The article by Prof. John Fraser superficial pain as an aid in the differential diagis of abdominal disease is of the thoughtful and ply informed nature which one is accustomed to ect from this authority.

he volume should receive a ready welcome from practitioners whose interest in their profession is icient to persuade them not to neglect the use of ks.

ROBIOLOGY.

Handbuch der biologischen Arbeitsmethoden. Edited by Geh. Med.-Rat. Prof. Dr. EMIL ABDERHALDEN. *Neurobiologische Studien am menschlichen Fœtus.* By M. MINKOWSKI, Zürich. *Methoden der Reflexprüfung beim Menschen.* By ARTHUR BÖHME, Bochum. Abt. V., Teil 5B, Heft 5. With illustrations. Berlin and Vienna: Urban and Schwarzenberg. 1928. Pp. 511–692. Mk.10.

rof. Minkowski deals with a hitherto relatively xplored field of neurophysiology, the material for study of which is bound to be meagre and difficult ome by. Most if not all of it has been obtained he help of colleagues, who have given him living ases procured during Cæsarean operations. The ibility of such organisms being dubious and in the ority of instances certainly brief, Prof. Minkowski found it essential to form beforehand a clear idea he exact experiments to be made and the time ts to be imposed for these, in each particular ; full details of his technique are supplied. king along these lines, he has been able to cover rprising amount of the field of antenatal neurosiology. His experiments have been directed ards investigation of the origination of movets in the fœtus; whether at the earliest stages romuscular activity is possible without interbion of the central nervous system. Reflexes and x movements of all kinds are examined, including se studied by Magnus and de Kleijn; the special senses, too, are not omitted. The electrical excitability of the fœtal musculature receives attention. Prof. Minkowski divides fœtal life somewhat schematically into "phases" described as embryonic or neuromuscular, early fœtal or spinal, middle fœtal or tegmentospinal, and late fœtal or pallido-rubrocerebello-tegmentospinal, respectively; his intention is to indicate, along the lines followed by Magnus, that at such and such an antenatal stage the fœtus is a "neuromuscular animal," a "spinal animal," and so forth. While this is doubtless correct enough in a physiological sense the discrimination is apt to lead to a rather artificial conception of neural activity. The monograph is peculiarly interesting and worth perusing by all those whose concern is with the nervous system.

Dr. Böhme's contribution is on clinical lines and deals comprehensively with reflexes in health and disease. In addition to those, both superficial and deep, with which the clinician has long been practically familiar, due attention is paid to the relatively novel reflexes and automatisms which in recent years have been elucidated by a number of workers, and which exhibit the activities of mechanisms at spinal and mesencephalic levels. The application of the researches of Magnus and de Kleijn to human pathological cases here receives full discussion and illustration. Altogether a very useful contribution to "reflexology."

RHEUMATIC DISEASES.

Being the Proceedings of a Conference on Rheumatic Diseases held at Bath on May 10th and 11th, 1928. Published by the Hot Mineral Baths Committee of the Bath City Council. Pp. 292. 5*s.*

THE proceedings at the important Conference on Rheumatic Diseases which was held at Bath under the presidency of Sir George Newman in May last were reported in these columns, several of the papers being published in full at the time or later. These proceedings have now been issued verbatim by the Hot Mineral Baths Committee of the Corporation of the City of Bath, and the volume forms a useful indication of the present state of our knowledge in regard to the incidence, causation, and treatment of many very common and obstinate pathological conditions. For convenience of reference the papers have been grouped under the headings of Social and General Aspects, Causation, and Treatment; a good index makes the record readily available for inquiry. On many important matters the papers show a diversity of opinion and consequently the need for further investigation, but along general lines the therapeutics represent the most recent work, and the book will be welcomed by medical practitioners as a help towards the elucidation of puzzling problems and a guide for routine treatment.

BOTANY.

A Practical Botany for Matriculation. By MARGARET A. SHUTTLEWORTH, Biology Mistress, Sydenham County Secondary School. London: University of London Press, Ltd. 1928. Pp. 272. 5*s.*

Miss Shuttleworth is already known as author of "The Wonders of the Human Body." Her aim has now been to supply a book, the subject matter of which will cover the matriculation syllabus in botany. It represents the minimum to be attempted in a two-years course and does not presuppose any previous course in nature study. In the experimental sections only the simplest apparatus has been described, pupils being encouraged to devise other methods of doing their practical work. The book is more than an examination manual, for it is interestingly written and excellently produced and illustrated. The author regards the relation between flowers and insects as the best basis for the study of the variety of flower forms, and the attention paid to pollination makes the manual of special interest.

HISTOLOGICAL TECHNIQUE.

A Guide for Use in a Laboratory Course in Histology. By B. F. KINGSBURY, Ph.D., M.D., and O. A. JOHANNSEN, Ph.D., Cornell University, Ithaca, N.Y. London: Chapman and Hall, Ltd.; New York: John Wiley and Sons, Inc. 1927. Pp. 142. 11*s*.

THIS book is designed as an introduction to laboratory methods and should prove of benefit to those who aspire to become laboratory assistants as well as to medical students. The authors, from their own experience, have made a conservative, and in many cases happy selection of the most applicable lines of procedure in histological investigations. Thus the inquirer is not faced with the problem of choosing from a bewildering number of alternative methods. Several notes on the difficulties commonly encountered in laboratory technique are given and a tabulated list of the causes of defects and difficulties in sectioning paraffin blocks should be of help to the beginner. Certain parts of the book may be criticised on the grounds that they are too sketchy to be of value, notably the section on the microscope and its accessories, which might well have been omitted. Figures depicting microscopes and accessories unaccompanied by descriptions are of little use.

HÆMATOLOGY OF CHILDHOOD.

Die Klinische Hämatologie des Kindesalters. By HEINRICH BAAR, Assistant at St. Anne's Hospital, Vienna; and EUGEN STRANSKY, General Assistant at the Imperial Institute for the Care of Mothers and Infants, Vienna. Leipzig and Vienna: Franz Deuticke. 1928. Pp. 481. 48*s*.

THIS work forms a useful pendant to the exhaustive monograph of A. Schittenhelm on blood diseases in general; pædiatricians and hæmatologists alike will find a great deal to interest them in these lucid pages. The hæmatology of childhood has quite legitimately been treated as a subject apart. It is regrettable that no two successive authors in this field can quite harmonise their nomenclature, but a liberal choice of synonyms is offered. An attractive feature is the full recognition of English-speaking authors in the excellent bibliography. The main sections of this work are on normal blood in childhood, the anæmias of childhood, "acute system-reactions," such as leukæmia, and the hæmorrhagic diatheses. A particularly valuable account of blood changes in infections of various types is included, and also clear discussions on the influence of faulty diet on the blood picture, and on the "anæmia pseudo-leucæmica infantum" and Banti's disease.

The book is likely to become a standard work of reference. In subsequent editions the illustrations might well be more ample, and the inferior photo-micrographs omitted.

SURGICAL ANATOMY.

By GRANT MASSIE, M.B., M.S., F.R.C.S., Senior Demonstrator of Anatomy and Surgical Tutor, Guy's Hospital Medical School. London: J. and A. Churchill. 1928. Pp. 413. 15*s*.

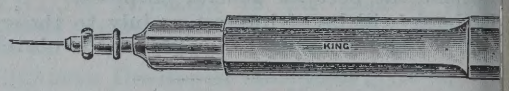
IT is difficult to break new ground in a subject like surgical anatomy; difficult, too, to keep the size of a volume within bounds and yet to include all that the ordinary student should know. There is nothing very original about this book, but the author has achieved the more important parts of his task with some success. He has given us a book easy to read and not too long, and yet sufficiently full for the needs of the student up for his finals. He states in his preface that his object has been to present anatomical facts attractively, and this also he has done. The illustrations are simple, clear, and informative, and the book should be popular.

New Inventions.

INJECTION TREATMENT OF VARICOSE VEINS.

(1) A NEW SYRINGE FOR INJECTING SCLEROSING SOLUTIONS INTO VARICOSE VEINS.

AS is well known, it is essential for a success injection that the sclerosing solution should com intimate contact with the inner coat of the vari vein in order to injure the endothelium; this in will be greater the more concentrated the inje solution. On the other hand, it is necessary to n



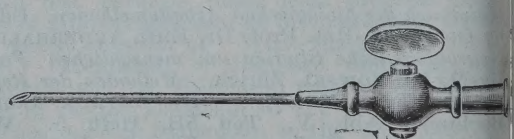
sure that the lumen of the vein has been entered, this is done by aspirating some blood; the blood drawn into the syringe is apt to reduce the concen tion of the sclerosing solution. It is therefore esse to aspirate as little blood as possible, and a syr which allows the smallest quantity of blood t clearly detected is indicated. I have used suc syringe for the last six months with most gratif results. The essential part of it is the long fine n made of polished glass, magnifying the extremely lumen. An infinitely small amount of blood is rea observed, which could not cause any dilution of sclerosing liquid; a fine short bevelled needle is with the syringe.

Messrs. Charles King, 34, Devonshire-street, Lon are the manufacturers.

Harley-street, W. A. A. MILLE

(2) NEEDLE FOR THE INJECTION TREATMENT OF VARICOSE VEINS.

THE needle here illustrated allows the syringe t detached without causing undesirable effects w the patient is changing from the standing to supine position, the prevention of loss of blood of air entering the vein. Through the body of



needle head there is a hole into which a loosely fit stop-cock is fitted. The stop-cock is "open" when cross-bar is in line with the long axis of the nee The stop-cock is fitted with a No. 17 needle, one inc length. In use, the needle, attached to the syring inserted into the vein while the patient is stand The syringe is then detached allowing blood to from the needle and then the tap is closed by a qua turn of the cross-bar. The patient then lies down the needle will remain undisturbed in the vein. limb is somewhat elevated and the nozzle of syringe lightly approximated to the head of needle, the cavity of which is gently filled the fluid to be injected, so as to expel the air f it; the syringe is then firmly attached, the tap ope and the injection made.

The needle is manufactured by Messrs. Allen Hanburys, Ltd., Wigmore-street, London.

H. ARTHUR MURRAY, M.B., Ch.B. Edin
M.O., Colonial Medical Service (Basutoland).

THE LANCET.

NDON: SATURDAY, SEPTEMBER 1, 1928.

OCULATION AGAINST ENTERIC FEVERS.

HE paratyphoid outbreaks have put many blems before practitioners in the affected districts. ong the more important of these are the recognition the disease in those who are unwell, and the sibility of preventing infection of the healthy abitants. Certain diagnosis of the enteric fevers doubtful cases owes more to the laboratory than s that of any other group of diseases, since at erent stages of the disease either agglutination s or microscopic examination of blood, urine, l fæces can be relied on to reveal infection. It is refore appropriate that the first of our new series articles on the Clinical Interpretation of Aids to gnosis should deal with the topical subject of agglu- ation tests in enteric fevers, and we draw special ention to the detailed advice offered by Dr. A. B. SHER as to the best methods of collection and patch of specimens of blood. The diagnosis ng established, the house-mates of the patient more than likely to demand advice as to means protection since they have realised how extremely omfortable an attack of paratyphoid fever may

It is, therefore, worth while to consider the age and nature of the vaccine which may be ployed for protective purposes.

The success of anti-typhoid-paratyphoid (T.A.B.) cine during the late war is familiar to everyone, l this preparation has been accepted as a con- ient means of safeguarding persons likely to be osed to the enteric group of diseases. The army cine was made up to a strength of 1000 million ed organisms per cubic centimetre—comprising million typhoid bacilli, 250 million paratyphoid and 250 million paratyphoid B. Half a cubic timetre (or 500 million organisms in all) was given the first dose, after which 10 days were allowed elapse before giving the second dose of 1 c.cm. 00 million mixed organisms). These quantities loubtedly produced a high degree of immunity, l there is certainly no reason for exceeding them civil practice, as is sometimes recommended. On contrary, it should be remembered that these doses of 500 and 1000 mixed organisms were ended for healthy men in excellent physical dition. They are probably too great for the rage male civilian and undoubtedly excessive for men. In prophylaxis by vaccines the ideal is a dual rise of immunity unaccompanied by un- asant "reactions." Military life makes a long ies of injections inconvenient, because this would an keeping the troops under observation for a siderable time; the number of doses is, therefore, reduced to two. Similarly, there may be reasons in civil life why the resistance should be raised immediately rather than at leisure—e.g., the presence of an epidemic—but it is wrong to suppose that two large doses producing two strong reactions at a week or ten days' interval is the only means of securing immunity. When there is plenty of time before exposure to infection there is no reason why a feverish reaction should not be avoided altogether by starting with quite small doses—even as little as 10 millions at first—and gradually building up the patient's powers of resistance. The immunity thus induced would probably be stronger than that obtained from two large injections. No vaccines are calculated to save a person who incurs successive infection by large quantities of virulent organisms; to ask this is to ask too much. If enormous doses of enteric bacilli are taken, as sometimes happens, for example, among mental patients of unclean habits, even recent immunisation might not actually stave off the disease, though it would probably prevent its being fatal. The usual aim of prophylaxis is to arm us against small accidental contaminations of food, and it need be effective no longer than there is danger of these occurrences. Immunity is a purely relative term, but, judging by agglutination tests, that conferred by paratyphoid A vaccine in ordinary dosage tends to disappear after about a year; typhoid immunity may possibly last three years, whilst paratyphoid B occupies an intermediate position. In civil life relatively small amounts of vaccine—e.g., three doses of 100 millions, 200 millions, and 500 millions respectively might be tried with advantage. Probably these are somewhere near the minimal quantities for securing rapid immunity to moderate infection in a male adult. If immediate protection by a single dose is wanted 500 million T.A.B. organisms should prove sufficient for practical purposes, and half this amount can give a considerable reaction. Inoculation is believed to be followed by a "negative phase" in which the subject's resistance is somewhat lowered, and this might be regarded as endangering individuals who are given typhoid vaccine whilst exposed to infection. It is hard to say when this phase begins and ends, but its significance has probably been much exaggerated. It is said to come on shortly after the organisms have been administered and to cease as the febrile symptoms abate. The negative phase affords no good reason for abstaining from inoculation. Nor are there many other reasons provided that the dosage chosen is not too large. In estimating the quantities to be given to children a calculation may be made on the basis of body-weight, though this does not hold good for very small children; when in doubt it is better to give less rather than more than the calculated amount. Apart from this it is enough to say that alcoholics react rather strongly; that renal disease requires especial caution; and that care and judgment are naturally needed where patients are enfeebled by disease or any other cause.

At the beginning of the late war it was found that soldiers inoculated with pure typhoid vaccine readily contracted the paratyphoid fevers. This shows that the killed typhoid organism confers a specific immunity, being powerless to protect the patient against others of the enteric tribe; so the typhoid element in T.A.B. does not appreciably reinforce the action of the A and B elements. As paratyphoid A is almost unknown in this country, and typhoid is not a serious risk in most localities, it would be sufficient in face of a paratyphoid B outbreak to give a pure *paratyphosus* B vaccine. The total number

of organisms given can thus be greatly reduced and the reaction—sometimes far from negligible—should also be diminished, though not perhaps in arithmetical proportion. To give the full anti-typhoid-paratyphoid vaccine for fear of a paratyphoid epidemic is like insuring against accidents by all means of transport when about to travel by aeroplane. Large doses of T.A.B., as now given with some freedom, are not likely to make inoculation popular, and it seems worth while to point out that they are seldom necessary.

THE LEGAL LIABILITY OF HOSPITALS.

IF a patient has some grave cause of complaint over the treatment he has received in hospital, it must surprise him to find how difficult it is to make the hospital liable in law for the actions of its expert staff. He may never have heard of the legal maxim *respondeat superior*, but he will know of frequent cases where an employer has been made to answer in damages for an employee's wrongful acts towards third parties. He will probably think of hospital and doctor as master and servant, for he will have an idea that the hospital exercises control over its expert staff by paying their salaries and by wielding the power of appointment and dismissal. But he will be wrong. These may be elements of the relationship between master and servant but—as Captain J. E. STONE makes clear in the careful analysis of the legal position which is concluded in our columns this week—these elements are not enough. The physician or surgeon on the staff of a hospital is nobody's servant. The hospital does not interfere with the prescriptions of the one or the operations of the other. The hospital's duty is to select a competent staff; it does not insure that the experts so selected will use that degree of care and skill which persons competent in that sphere may be expected to use. This limitation upon the doctrine of *respondeat superior* is by no means confined to the medical profession, but it happens to have been affirmed in three cases in which medical treatment was in question.

In the first of these (Hall *v.* Lees, 1904) a plaintiff complained that she had been injured by the negligence of a nurse provided by the defendants who were an association existing to supply duly qualified nurses. It was held that the association only undertook to supply a competent nurse for the patient, not to nurse the patient; the nurses had to follow the directions of the patient's doctor and the association was not responsible if a nurse failed to exercise due care and skill. Two years later, in Evans *v.* Liverpool Corporation, a jury found that the plaintiff's son had been discharged too soon from an infectious diseases hospital provided by the defendant corporation. He was sent home before he was completely recovered from scarlet fever, and consequently his brother and sisters were infected. Mr. Justice WALTON held the defendants not liable. "They do not undertake the duties of medical men or to give medical advice, but they do undertake that the patients in their hospitals shall have competent medical advice and assistance." The doctor in charge was admittedly competent and so no blame attached to the corporation for employing him. Finally, in Hillyer *v.* St. Bartholomew's Hospital the Court of Appeal put the matter beyond doubt in 1909. A patient somehow received burns while under an anæsthetic on the operating table; he sued the hospital but his claim failed. Lord Justice FARWELL said it was impossible to contend that the surgeon or the acting assistant surgeon, or the house surgeon, or the anæsthetist were servants of the hospital in th proper sense of the word. They were all profession men employed by the hospital to exercise the profession to the best of their abilities according t their own discretion; in exercising it they were i no way under the orders of the hospital or bound t obey its directions. A similar principle applied t the nurses. "The nurses and carriers assisting at a operation cease for the time being to be the servan of the defendants (the hospital), inasmuch as the take their orders during that period from the operatin surgeon alone."

As Captain STONE is careful to point out, Lor Justice KENNEDY, while concurring in the court decision, added a qualification. "It may well be, he remarked, "that the hospital authority is legall responsible to the patients for the due performanc by their servants within the hospital of their purel ministerial or administrative duties, such as, fo example, attendances of nurses in the wards, sum moning of medical aid in emergency, the supply o proper food, and the like." Hospitals, therefore, appears, must distinguish between the matters o professional skill in which the hospital board will no interfere with physician, surgeon, or nurse, and th "purely ministerial or administrative duties" whic the board is responsible for regulating. Presumabl it would be for the jury to apply the distinction t the facts of a particular case. But a jury could hardl decide without giving due weight to the evidence o the medical profession on what would be largely matter of professional practice. The same remar applies to those occasions where there is a questio of the relative responsibility of nurse and medica practitioner as in a recent case where a patient wa scalded by a hot-water bottle. If the profession ca achieve unanimity in its evidence regarding th particular functions delegated by physicians o surgeons to nurses, the court and the jury are no likely to take a different view.

DENGUE IN ATHENS.

AN epidemic described as dengue fever ha attacked the inhabitants of Athens and th Piræus during the last few days. The number o cases is reported to be between 160,000 and 200,00 All business is paralysed and many shops, office and factories have had to close down owing to th illness of their staffs. The leading bank, with normal staff of 180, is now carrying on with onl 20, while Government departments are quite di organised. The epidemic is now spreading to th provinces, whither Athenians have fled to avoi contagion.

Dengue fever is best known as an endemic infectio in the coastal regions of India, China, the East Indie and throughout the Pacific islands. Many wide spread epidemics have been recorded since MANSO first described the virulent outbreak in Amoy i 1872, which completely paralysed the small Europea population of the town and attacked 95 per cent. o the Chinese population. The exact method o conveyance of the disease was at that time unsu pected; but MANSON recorded with characteristi fidelity the sudden onset, the excruciating bon pains which have bestowed the synonym of "dandy or "breakbone fever" on the affection. Othe peculiar features—the double crisis of fever, th purpuric rash, and the post-febrile bradycardia—wer also noticed in the Amoy cases. To show the sudde onset of symptoms it is recorded that victims attacke

le shaving would drop a razor to the ground n a helpless hand. Since that period dengue has ırred at intervals of years in epidemic waves, nly in the early autumn months. In Europe it appeared in Southern Spain, Gibraltar, Malta, key, and, notably in 1881, in the Ægean Islands. Asia Minor serious epidemics have occurred in ʏrna, Cyprus, Beirut, Jaffa, and Jerusalem. ile normally a coastal disease, in its pandemic n dengue spreads a considerable distance beyond usual confines and may even, in Syria, ascend ıntains to a height of 5000 feet. That the disease pread solely by the agency of mosquitoes has been ɔgnised since the original observations of H. GRAHAM Beirut in 1903. At that time he suspected that carrier was the common brown mosquito *Culex ɟans*, though since then the carefully conducted eriments of CLELAND, BRADLEY, and MCDONALD, Australia, have incriminated the common "tiger quito," *Aëdes argenteus* (formerly known as *omyia fasciata*) as the sole vector. The exact ıre of the dengue virus is unknown, but the arches of CLELAND and his fellow workers e shown conclusively that the virus is attached ıgglutinated to the red blood corpuscles and can s through the pores of a Pasteur-Chamberland r. J. F. SILER has demonstrated that the blood lengue is infective to the mosquito for 18 hours ɔre the onset to the end of the third day of the ɛss. The mosquito, after imbibing dengue blood, s not become infective for 11 to 14 days, but ɛafter remains so for the rest of its life.

or the development of an epidemic the vector ɜt be present in large numbers, and this lies defective sanitation and abundant opportities, in the supply of stored water in close ɛimity to the houses, for the mosquito to breed; hort, the conditions which favour the spread of gue are similar to those conducive to yellow ɛr. At the present moment conditions in Athens must ınusually favourable to the propagation of *Aëdes nteus*. As regards potential disability during an ck dengue is serious enough, but as a rule it leaves permanent serious sequelæ in its wake, and the tality-rate is very low. Perhaps it is for this on that no specific pathological lesions, gross or roscopic, have been discovered. Unfortunately present epidemic at Athens appears to be excepal in having a high mortality-rate, the attacks ıg often fatal. Probably, however, the infection is ng only those who are the subjects of grave heart ɛidney disorders, where it acts as the immediate ɜe of death. If dengue is the sole cause it ɜt be of an unprecedented virulence. Another ɜibility is that the epidemic may be due to some ɛr infection. If it is dengue there is no prospect ıbatement until the advent of the cool weather, ch cannot be expected for another two months.

OST-VACCINAL ENCEPHALITIS.—The Small-pox Vaccination Committee of the Health Committee of League of Nations met at Geneva on August 22nd ɛr the presidency of Dr. R. Jorge, of Portugal, to consider among other questions. A report has been drawn n which the rarity of these cases is emphasised, in parison with the total number of vaccinations in any ıtry. The committee points out that children between d 13 years of age are particularly susceptible, whereas ıts and adults are hardly ever affected; this age incidence ɛsts the inadvisability of postponing primary vaccina-, which is the most powerful weapon available against l-pox, until after infancy. The appearance of encephs is not held to be associated with any particular strains ɛmph or with accidents in preparation. The committee lude, on the evidence available, that post-vaccinal phalitis is distinct from encephalitis lethargica.

Annotations.

"Ne quid nimis."

THE COPENHAGEN CONGRESS.

THE First International Congress of Oto-Rhino-Laryngology, which was held at Copenhagen at the opening of last month under the presidency of Prof. E. Schmiegelow, was fully attended. The meetings were held in the Christiansborg, the Danish Houses of Parliament, and the opening ceremony was honoured by the presence of the King of Denmark. The amount of material was so great that the Danes generously forwent the reading of their papers. There were four main subjects for discussion: (1) Septicæmia as a result of pharyngeal infection, opened by Prof. W. Uffenorde (Marburg) and G. Ferreri (Rome), the opening with excellent lantern slides showing invasion of vessels in the neck by organisms. (2) The conservative radical operation, by Prof. H. B. Neumann (Vienna), well illustrated by slides of microscopical sections to show bony changes going on in apparently healed radical operations. Mr. H. Barnett (Bath) followed, condemning the radical operation. Considerable discussion took place, but nothing really new emerged. (3) The influence of anatomical structure of the middle ear on the course of suppuration therein by Profs. F. J. Moure and G. Portmann (Bordeaux) and by Prof. K. Wittmaack (Hamburg). This is a subject on which otologists in this country have long held definite opinions, led by Mr. A. H. Cheatle. (4) Surgical diathermy for cancer of the pharynx, larynx, and œsophagus, opened by Dr. Dan McKenzie, followed by Mr. Norman Patterson (London); a strong case was made out for removal of growths by the diathermy knife instead of the cold knife. In the subsequent discussion papers were given by French and Spanish authors. The shorter papers read at the Congress dealt with practically every branch of the specialty. To mention one or two that were outstanding: Dr. A. Pohlman (St. Louis, U.S.A.) spoke on "minimal audition"; experiments on this subject had been made with an audiometer and many interesting observations emerged, notably that lengthened bone conduction is apparently not real. This property was, however, vigorously sponsored by clinical observers of the German school. It seems that the audiometer has not been given enough attention in this country. Dr. Wells Eagleton's (Newark, U.S.A.) study of sixth nerve involvement in connexion with the early diagnosis of meningitis called forth some interesting discussion. Dr. E. Huizinga and Dr. C. E. Benjamins (Groningen) brought forward some interesting work on ablation of parts of the internal ear in pigeons; they found that destruction of the lower part, including the saccule, produces no demonstrable effect on the movements of the birds; while ablation of the superior part containing the utricle and three ampullæ has the same result as complete destruction of the labyrinth. Mr. V. E. Negus (London) put forward in his paper the ingenious suggestion that the function of the cricopharyngeus sphincter was to prevent air passing into the œsophagus during inspiration. In addition to the scientific work there was much entertainment offered by the President, the Committee, and the civic authorities, and Dr. N. Rh. Blegvad deserves a special word of mention for his all-embracing labour as general secretary.

PINEAPPLE JUICE.

CHILDREN have always preferred the raw pineapple, when obtainable and however crude, to the uniform and refined product in sealed tins; and their choice is wise, for, as the *Journal* of the American Association has reminded us again, fresh pineapple juice contains an active proteolytic enzyme known as

bromelin, which is destroyed when the juice is heated or the fruit is canned. No doubt both clauses are true when canning implies heat; but our own chemist pointed out a quarter of a century ago that, while the peculiar digestive agent of pineapple is destroyed by cooking, there is no reason why tinned fruit should not retain its digestive power, provided that the pineapple is not preserved by heat. Bromelin, as we then showed, would digest as much as 1000 times its weight of protein, whether of meat or eggs, within a few hours, and there is an abundant supply of the enzyme in the pineapple for the average sized pine will yield nearly two pints of juice. Unlike pepsin, the digestive principle of the pine appears to operate equally well in an acid, neutral or alkaline medium. There would therefore be more justification for eating pineapple and beefsteak together than there is in eating red currant jelly with roast mutton, although we may reasonably assume in the latter case that it was because an enzyme accompanied the pleasant taste that this culinary constellation arose and retained its sway. Bromelin must not, of course, be confused with bromalin, a combination of hexamine and ethyl bromide which has had some vogue in neurasthenia and epilepsy. It is curious that Remington's Practice of Pharmacy, which is such a complete collection of drug lore in America, contains no mention of this pineapple enzyme, although it is mentioned in Tibbles's Foods and is well recognised so far afield as in Mayerhofer and Pirquet's Lexikon, and in Nadkarni's Indian Materia Medica.

THE LATE INFECTIVITY OF SCARLET FEVER.

IT used to be thought that after about six weeks, and the completion of desquamation, the scarlet fever patient was free from infection. Later it came to be noted that after the discharge of scarlet fever patients from hospital a fresh infection occasionally arose in the home. For example, in 1894 Dr. A. K. Chalmers reported that among 2593 patients discharged from the infectious hospitals in Glasgow fresh cases appeared in 70 of the houses to which they were sent. An investigation set up by the Metropolitan Asylums Board culminated in a lengthy and valuable report [1] by the late Dr. A. G. R. Cameron in 1904. In this report he emphasised—what was already known to many—that it was the convalescent with unhealthy mucous membranes who was more likely to be infectious and that there was no evidence of infection arising from late desquamation. Of late years there has arisen a tendency to curtail the detention period of this disease. In his report [2] to the Ministry of Health Dr. Allan C. Parsons gives information concerning the minimum period of detention of uncomplicated cases in 46 hospitals. The authorities of 15 of these required 42 days detention as the minimum, one 40 days, three 35 to 42 days, six 35 days, one 30 days, eighteen 28 days, and two 21 days. Thus it will be seen that 25 observers do not differ much from the old dictum. There is little doubt that a number of sufferers from scarlet fever are free from infection at the end of four weeks and probably earlier, and if diphtheria can be taken as an analogy it is certainly so, but the difficulty is in picking out those who are free from infection from those who are not. It is admittedly unsafe to consider free from infection those who suffer from a pathological condition of the throat or of the nose, or those who may have an unhealthy condition of an ear. But it is not always easy to decide that the tonsils are quite normal, and it may be quite impossible to discover a tiny nidus of infection in the small nasal passages of a young child. It may be said that this is also so at a later stage of the disease, but it is to be remembered that the natural tendency of the human being is to rid himself of infection and therefore the risk in early discharge is greater. In detecting infection in similar cases of diphtheria careful bacteriological examination is some help, but this can hardly be said of scarlet fe for it is difficult to differentiate the streptococcus this disease from other hæmolytic streptococci. the whole, therefore, and admitting our want precise knowledge, it may be considered wise to reg scarlet fever patients who show no patholog condition of the throat, nose, or ear as possi infectious for a period of about five or six weeks a the onset of the disease. There is ample evidence t the late desquamation is not in itself infectious, a there is no definite evidence that the earlier desqua tion is capable of causing infection to others. On other hand, patients suffering from pathological cor tions of the nose or throat should not be conside free from infection until recovery from them taken place. A discharge from the ear does appear to be so fruitful of infection, and consequen some observers consider it comparatively safe discharge such cases at the end of three months. is easy, even for the experienced, to fail to obse some small unhealthy area of the mucous membra and it should always be borne in mind before declar a patient to be free from infection that a m careful examination should be made.

ALUM IN BAKING POWDERS.

FOOD prepared by modern methods frequen contains small quantities of constituents, the preser of which is not suspected either by the consumer his physician, and which by their long-continu action may set up symptoms which are distressi to the one and puzzling to the other. Five work at the Institute of Physiology of the University Strasbourg [1] have investigated the effects of "mine leavens" or baking powders containing alum; matter which is not new, but which, having rega to the very different views held in Europe and Americ fully justified reinvestigation more especially as t Strasbourg workers, as they point out, have consider the physiology rather than the gross toxicology of t question. They say "we would like to show by precise example to what social dangers we are expos through the daily use of products which have justification from the physiological point of vie but only mean a slight economy of time to cooks a housekeepers." This way of looking at things may w be commended to those who would suffer the additi of boric acid to food.

The American tolerance of alum in baking powde which the health authorities of most Europe countries virtually forbid—even in blockaded Germa when potassium bitartrate could not be procure "hygienists" we are told, "severely opposed the selves to the production or sale of mineral leave containing alum, even as an *ersatz*"—is due to t belief that if the powder is a scientifically calculat mixture of acid calcium phosphate, alum, and bica bonate of soda, all that remains in the bread wh the reaction is finished will be sodium sulphate, ac sodium phosphate, calcium carbonate, and aluminiu phosphate. The insolubility of the last substance apparently assumed. As a matter of fact, althou the Strasbourg workers do not refer to it, W. Bigelow and C. C. Hamilton in 1894 [2] concluded th the influence of alum in flour on digestion was ov estimated, but that, notwithstanding statements to its insolubility, aluminium phosphate had retarding effect on gastric and pancreatic digesti in vitro, while two years earlier O. Hehner had sho by experiments on himself and two assistants th baking powder containing alum when taken alo caused diarrhœa and painful indigestion. Comparati experiments on mice have shown Schaeffer that bre containing aluminium phosphate gives rise to

[1] The Dangers of Certain Mineral Baking Powders Based Alum, when Used for Human Nutrition. By Georges Schaef G. Fontes, E. Le Breton, Ch. Oberling, and L Thivolle. Jour of Hygiene, August, 1928.

[2] Jour. Amer. Chem. Soc., xvi., 587–597.

cellular necrosis of the superficial epithelium of stomach and of the tops of certain intestinal villi, e lesions greatly resembling erosions found in an pathology. When dogs are fed with similar inous bread lesions are not formed in either ach or small intestine, but in the large intestine, especially in the descending colon and the sigmoid re. Further, there seems to be a specific action e aluminium ion on the ovary, as the productivity male mice is much diminished if they are fed on aluminious diet, and the offspring succumb more y to infantile disease. Anatomo-pathological ination confirms these experimental results in a ing manner. While in the case of male mice ng absorbed aluminium the testicles remain al and the spermatogenesis active, the female show characteristic lesions of the ovaries.

ie Strasbourg chemists' concluding paragraph is worth reproducing: "We hope," they write, it this summary of our researches will be sufficient ake clear the nature of the danger spoken of at beginning of this article. We see that certain es, not poisons in themselves in the usual sense of word, can provoke physiological disorders and nic lesions, the ætiology of which remains ally unnoticed, when they are absorbed daily for hs and years. Such products are most certainly nsible for many illnesses, the frequence of which ients with the alimentary conditions imposed on y modern civilisation in a manner inexplicable ehand. Our object will have been attained if ucceed in attracting the attention of physicians ygienists to certain problems, the study of which rhaps not very attractive, but the solution of n is of considerable practical interest."

MEDICAL RELATIONS OF LAFONTAINE.

E author of the celebrated "Fables" was by eans an admirer of the medical practice of his yet he associated on friendly terms with quite mber of physicians, some of whom were distin-ed in their day. On the mother's side he was nded from two royal physicians, and he had maternal uncles who practised medicine. Yet, . George Morin writes,[1] he does not seem to have ited any therapeutic instincts from his medical ars. His mother was Françoise Pidoux, whose y was well-to-do and important in Poitou for years. The great-grandfather of the poet François Pidoux, who received his diploma of or at Montpellier, and settled in Poitiers instead s native town of Châtellerault, became the doyen ie medical faculty of Poitiers, and waged war st charlatans of all sorts, of which Poitou was rs a happy hunting-ground. He also insisted on pplication of the edict of Blois which prohibited ale of medicines by druggists, except on medical ription. This was in 1541—so long has been truggle against counter prescribing! François ix was called in to treat important personages t length was appointed first physician to King y II. He died in 1600, leaving the family of ix among the most influential in all Aquitaine. second son, John, following in his footsteps, ed under his father in Poitiers and became nal physician to the Duke of Anjou, afterwards y III. of France, whom he accompanied on an ition to Poland, on which occasion he proved to the father of Cardinal Richelieu and secured vour. On the accession of Henry IV. he became is physician. Jean Pidoux was the author of rst book in French on hydrotherapy and balneo-He published, in 1587, a treatise on "La et usage des fontaines de Pougues en Nivernais cours qui peut servir aux fontaines de Spa et s de pareil goût." Not content with his rate of Poitiers he obtained 20 years later the r degree at Paris. His inaugural thesis was entitled De Febrium Curatione. He lived in influential and literary society in Paris and was employed in various important political and social affairs connected with the Court. His ambition to shine as an author of verse was not gratified, for his efforts, says Dr. Morin, are not worthy of the grandfather of the author of the fables. If Lafontaine inherited from the Pidoux no aptitude for the practice of physic, he seems at least to have received through his mother their love of good cheer and of good company and their capacity for enjoyment. He describes in a letter to his wife a visit to one of the Pidoux of Châtellerault, a kindred spirit who at the age of 80 was full of the joy of life. Dr. Morin concludes by deciding that Lafontaine was a regular Pidoux, a Pidoux full of life and spirit, imaginative, light-hearted, and frivolous.

hérédite médicale de Lafontaine, Paris Médical, 1st, 1928.

A NEW ANTHELMINTIC.

THE search for a vermicide harmless to man continues. Dr. J. Chevalier[1] brings forward the claims of two pyrethrines obtained from *Chrysanthemum cinerariaefolium*, the insecticidal pyrethrum, and isolated by fractional distillation in vacuo. They are non-crystalline, insoluble in water, but easily dissolved in organic solvents, and can readily be rendered almost inert by saponification. It has been found impossible to kill warm-blooded animals by oral ingestion or by subcutaneous injection of these substances, though intravenous injection at the rate of 2 mg. per kg. of body-weight produces clonic convulsions, and 6 mg. is fatal. On the other hand, cold-blooded animals such as fish. leeches, earthworms, and frogs die in dilutions of from 1 in 1,000,000 to 1 in 3,000,000. Classing intestinal worms as akin to cold-blooded animals,Chevalier found experimentally that *Ascaris lumbricoides* of the pig and tænias of the dog became detached and convulsive, and presently died when placed in a "dilute" solution of the drug. Experiments in the treatment of animals are reported as successful, and excellent results are said to have followed its use in human beings infected by various worms and by giardia; the drug is also being tested on the hookworm in Egypt. Detailed reports of the dosage used and of the grounds on which these conclusions have been reached will be awaited with interest, seeing that the preliminary note is silent on these essential matters.

THE LATE SEQUELÆ OF EPIDEMIC ENCEPHALITIS.

THE serious prognosis of the later manifestations of epidemic encephalitis, to which we drew attention in a leading article on June 30th, is confirmed by the studies of Dr. Lloyd H. Ziegler, published in the *Journal of the American Medical Association* of July 21st. Working from the Mayo Clinic he has followed up 752 patients who had attended the clinic for epidemic encephalitis during the period 1918 to 1927. The mortality-rate for this group was low at 13·2 per cent., but on the other hand the complete recovery-rate was only 1·3 per cent.; of the total number of patients 15·7 per cent. were able to work regularly, and 25·7 per cent. were able to do light or part-time work. Unfortunately there is little doubt that the work figures for the same group of patients will diminish in time, owing to the fact that the condition usually progresses slowly, and many of the patients in the series only had their attack within the past four years. Half of them developed chronic sequelæ immediately after the acute attack; nearly 10 per cent. recovered entirely from their acute attack, only to develop chronic sequelæ 15 (average) months later, and in one case the latent period was actually seven years. Fully a quarter of the patients exhibited a residual stage practically indistinguishable from post-influenzal debility for 14 (average) months before

[1] Bull. de l'Acad. de Méd., 1928, xcix., 446.

sequelæ emerged, and no fewer than 15 per cent. of these patients are now Parkinsonians. The mental aspect does not appear to have received the same careful attention as the neurological in this investigation, only very obvious symptoms being recorded. There seems little doubt that when the encephalitic temperament is more generally recognised it will be appreciated that the chronic invalidism of the encephalitic is due as much to mental as to physical disabilities. The lowering of emotional values, the craving for sympathy and attention with exaggeration of physical deficiencies, and the childish outlook and lack of concentration of the average encephalitic are often more important factors in the economic question of ability for self-support than are the tremors, mild rigidity, ocular symptoms, and other neurological manifestations. The futility of our present methods of treatment of this disease is brought out by Dr. Ziegler's study. All the recognised methods were tried in this series of cases, and apart from the undoubted value of scopolamine as a palliative measure in Parkinsonism no therapy can be regarded as of any appreciable value. At the Mayo Clinic sodium cacodylate is regarded as a useful tonic, and supplemented by good general care and attention to obviously active foci of infection forms the usual method of treatment. Streptococcal vaccines, autogenous or prepared from patients with similar disorders, have been extensively used at this clinic, but the results obtained were no better than with other therapeutic measures. It appears that the most hopeful sign in the realm of this disabling disease is the steady diminution in the number of fresh cases which has occurred in each succeeding year since the severe epidemic of 1924.

LOCAL MALARIA CONTROL IN BENGAL.

Birnagar or Ula, credited with being the place whence spread the disastrous malaria epidemic of 1856, is one of those half derelict towns so frequent in the upper Gangetic delta, with a population of 2300 in place of the 40,000 of 70 years ago before malaria, speaking without metaphor, laid it waste. Five years ago some inhabitants, stung by the position, formed a local public health society, whose keen honorary secretary has just issued one of his periodical reports.[1] Funds are supplied by considerable private subscriptions, by a substantial grant from the Bengal Government, and by a large gift of quinine from its director of public health. The antimalarial measures used have been the oiling of anopheline breeding-places and a wide administration of quinine. The difficulties encountered in this private enterprise have been those familiar when such campaigns have been attempted in India by Government officers. There has been some stubborn opposition to oiling, two and a half out of eight and a half miles of water edge in the small area actually covered having had to be left unprotected. These untreated tanks have bred larvæ profusely, and it is significant that while the municipal authority has contributed generously to the funds of the society, the municipal tank is not one of those which the society has been permitted to oil. Some of the observations made have a wide applicability. The washing of muddy water into tanks was followed by destruction of all larvæ, breeding recommencing immediately as it settled and cleared. While, apart from this, mosquitoes bred continuously they did not torment human beings during dry weather, but as soon as rain fell entered houses and bit, while the malaria-rate rose after the usual interval. It is believed that in dry weather the insects remained inactive in the all-embracing jungle, and that this is also the explanation of the immediate but temporary influx of mosquitoes into houses when neighbouring jungle is felled. Such clearance has been begun with sale of wood and cultivation of land, but permission for further clearance is being withheld by owners. The future is not looked forward to with hope. It is felt that the determination of the mosquito species most implicated locally in transmitting mal requires more expert knowledge than is available the spot, but it is, after all, improbable that ungrudging coöperation of the Bengal Malaria Rese Laboratory, already afforded in identifying la will not be extended to the dissection of mosqui locally collected, a subject particularly appropri It is believed, too, that the local campaign shoul merged in a wider one to be undertaken, the wi suggests, by the District Board. If certain indicat in the report are read aright it is questionable whe anything will replace adequately an enthusiastic l patriotism.

CHEMISTS AND BENZOL.

We owe to research in America, originated industry,[1] the disclosure that benzol possesses defi toxic properties. When its fumes are regul inhaled in a strength of 100 parts per 1,000,00 air the hæmopoietic organs are attacked, and ana follows with decrease of polymorphonuclear leucocy Industrially benzol is used as a valuable solv particularly of rubber. Fortunately less toxic solve such as toluol, xylol, or high flash naphtha, ca substituted, and it has never come into widespread in English factories. Now a useful note [2] of war is given to chemists working in laboratories, who notoriously careless about exposing themselves unnecessary risks. They are urged to confine the of benzol to testing, and to abolish it as a clean agent for which it is far too often used in profus If for any reason continued exposure is unavoida the chemist should place himself under me examination once every month or two. Chem tend to disregard the fact that the human body delicate reagent always ready to react when exp to unsatisfied compounds, of which benzol is one

THE PHYSIOLOGY OF FASTING.

Many religions exhort believers to fast for the g of their souls, and most unqualified and some quali schools of medical thought advocate occasional f ing for the good of the body. There is no doubt some degree of reduction in the diet produces excel results in a great many persons, but there is n uncertainty about the mechanism by which t results are produced. Prof. P. F. Richter holds view that for lack of knowledge of the physio of hunger a valuable therapeutic weapon is b neglected. In a recent address[3] to the Berlin Soc for the Study of Internal Medicine he dealt exh tively with hunger from the clinical point of view. syndrome is, he says, primarily a defence mechan Deprived of a part of its supplies, the orga promptly adapts itself for work on a restricted int It reduces its combustion rate and institutes econ in all its departments. By lessening the pang hunger it enables itself to endure the new condit as long as possible. Fasting is, therefore, an effe means of lowering the metabolic rate at need. of the most important fields for its use is diab and research into the biochemistry of hunger w almost certainly elucidate many diabetic phenon which are as yet unexplained. What evidence t is suggests that the effect of hunger on the ne and musculature is rather to improve their condi than to do them any harm. It causes a slight fa blood pressure, but a constant level is soon reac A change from a meat to a vegetarian diet, accor to O. Müller and M. Gänsslen, quoted by Ric improved the state of the peripheral circulation; is because meat proteins cause spasm of the arter and dilatation of the capillaries, a condition whi rectified when they are removed from the diet.

[3] Deut. Med. Woch., 1928, i., 1067.

ictims of Graves's disease fasting is indicated. ime researches showed that compulsory semi- ation was beneficial to over-active thyroids, and probably this action on the thyroid which mines the drop in basal metabolism. Fasting to have no deleterious after-effects. Oxida- s apt to be somewhat unduly rapid when the is first broken, and the cells show such a capacity for absorbing protein as seems to con- t all the known laws of nitrogen metabolism. ding to Richter, fasting should benefit dis- s of carbohydrate metabolism (although the eas may suffer in diabetic patients) and spastic lers of the blood-vessels such as glomerulo- itis. In allergic conditions such as migraine, psia, epilepsy, and asthma it acts by reducing take of foreign proteins. The leakage of protein he blood stream through the intestinal mucosa ponsible for a multitude of ailments, and the tion in the membranes is thought by some rs to be due to an interference by unwise dieting the balance of flora in the bowel. A fast will restore this balance. Fasting for high blood re is, in Prof. Richter's opinion, not indicated, the pressure is not appreciably altered. Sum- up, he likens its action to the stimulation of a n protein, but gives a warning that the estima- f the patient's tolerance is a difficult matter.

AMYLOID DISEASE.

E cure of three out of 15 patients in whom the nce of amyloid disease was definitely proved is led by Prof. J. H. Waldenström in a beautifully rated monograph [1] on the formation and dis- rance of this condition.

e author is unable to tell us anything new about emical structure of amyloid. He notes that it is tein substance rich in tyrosin, and suggests that xic effects of prolonged suppuration prevent the tion of certain unknown proteolytic enzymes; e absence of these the body becomes saturated this protein substance which is deposited along sceral blood-vessels. As a result of considerable al and pathological investigation he holds that yloid occurs at all it is invariably found in the where it is evenly distributed. A further vation made is that a liver may be rich in peri- lar amyloid deposit and yet show no enlarge- because of the tendency for the amyloid is to crush the liver parenchyma. Prof. enström believes that a mixed infection is sary for the production of amyloid, but in spite eful search he could not incriminate any parti- combination of organisms. By protein satura- he produced amyloid in mice. He found that ouse in four is amyloid-immune, and believes here is a similar constant proportion of human ts amyloid-immune. The production of amy- eems to take about two years from the time of tablishment of the septic focus; and about the period is required for its eradication. Prof. enström's treatment for the causative surgical is conservative; at his hospital the patients a big sunny verandas, and are given abundance ter and cream. The diagnostic methods adopted pected amyloid disease are drastic, but leave no as to the nature of the condition. A trocar annula similar to a lumbar puncture needle, t that its calibre is 1½ mm., is thrust into the and the trocar is withdrawn. The cannula is forwards about 2 cm. and twisted slightly in g axis. A rod of liver tissue is thus cut, with- n from the cannula by a powerful little n syringe, and examined microscopically. In of the three cured cases at least three liver ures were made, and by sections of material so ned Prof. Waldenström demonstrated succes- over a period of about three years normal liver tissue, liver tissue stuffed with amyloid deposit and finally restored normal liver tissue. In THE LANCET of July 21st Dr. G. F. Walker recorded a case of amyloid disease of considerable duration which yielded to treatment, and we welcome this further evidence that a disease which was long held to be both common and fatal is now not only rare but also in certain conditions curable.

[1] Act. Chi. Scand., 1928, lxiii., 479.

STRONTIUM FOR MIGRAINE.

GOOD results from a new method of treatment of migraine are reported by Dr. Max Serog, of Breslau, in a paper [1] which has just been published. Having found, in occasional instances, an improvement after intravenous injection of a preparation of strontium, he made a systematic trial of treatment with this metal and now reports the results in 20 cases. All the patients experienced great relief; many of them suffered previously from very frequent attacks, and, after a course of strontium, were free from headaches for many weeks; some are described as being "quite free" from attacks but, unfortunately, it is not stated how long such patients were kept under observation. The preparation used by Dr. Serog was "neostrontan," made by the firm of Tosse, Hamburg. Five cubic centimetres of a 10 per cent. solution of this strontium derivative were given intravenously, followed at intervals of two days by two injections of 5 c.cm. each of a 20 per cent. solution. The injections were well tolerated; the only unpleasant symptom was a feeling of heat or flushing of the face, and this could be greatly reduced if the injection was given very slowly and, when the flushing began, temporarily stopped until it had passed off. The best results were obtained with the younger patients. It is noteworthy that in several cases it was possible to cut short an attack of migraine by giving an injection of neostrontan—even when the attack was at its height. It seems that this treatment is capable of attaining successful results, especially in cases in which the attacks are very frequent, and it may be used either in combination with other methods or where other methods have failed. But the path of the physician is strewn with discarded remedies for migraine.

CURRENT VITAL STATISTICS.

ON another page we deal with some of the lessons which may be drawn from the text of the Registrar-General's Review of the year 1926. In the meantime the early appearance of Part I. (Medical Tables [2]) of the Review for 1927 has almost bridged the gap between the two years. The salient features of this review were embodied in a provisional statement,[3] which has, of course, not been substantially modified. The birth-rate of 16·6 for the year 1927 is the lowest rate recorded since the establishment of civil registration in this country, the lowest rates previously being those for 1918 (the last year of the war)—viz., 17·7 and for 1926—viz., 17·8 per 1000 population. The death-rate was 12·3 per 1000 population, slightly higher than for any year since 1922. The rise affects the two sexes almost equally, and was due to a severe epidemic of influenza in the March quarter. The death-rate in the June quarter was the lowest on record for the second quarter of the year, while the rates in the third and fourth quarters were below the average rate in the corresponding quarters of the last five years. The deaths of infants under 1 year of age were equal to 70 per 1000 births, being the same as for the previous year; thus the two years 1926 and 1927 have the lowest infant mortality-rate on record except only that for 1923—viz., 69. The mortality from the infectious diseases differed little from that for the previous year, except that the deaths from influenza numbered 22,263 and were equal to a rate

[2] H.M. Stationery Office. 15s.
[3] See THE LANCET, 1928, i., 141.

of 567 per million living. The mortality-rates recorded in earlier epidemics were as follows:—

1848 .. 459	1892 .. 533	1918 .. 3078	1922 .. 563
1891 .. 574	1900 .. 504	1919 .. 1181	

From these figures it will be seen that the mortality in 1927 was the highest recorded since the great epidemic of 1918–19, and was but 7 per million below that of 1891. The increased mortality from pulmonary tuberculosis and heart and respiratory diseases may also be in part due to the prevalence of influenza. The death-rate from cancer was 1376 per million population, or 14 per million higher than in 1926, being the highest crude death-rate yet recorded. The 4907 deaths from suicide were equal to a rate of 125 per million, which is the highest recorded rate from this cause; the rates in the three preceding years were 96, 105, and 114. The Review indicates the increasing use of lysol and coal-gas as means of self-destruction.

Prof. Robert Muir, Sir John Parsons, and Sir Charles Trevelyan have been appointed members of the Medical Research Council, succeeding Prof. G. Dreyer, Sir Archibald Garrod, and Mr. William Graham.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

(DENTAL BRANCH.)

IN the Educational Number of THE LANCET last week, when placing before our readers the advantages offered by joining this Service, we were unable to give the following current rates with regard to Dental Officers, the information not arriving in time for press.

On the completion of two years' service in the rank of Surgeon Lieutenant Commander (D), dental officers on the Active List are eligible for a three months' post-graduate course at a dental hospital and school at the public expense, and will draw full pay while attending the course.

Pay.—The current rates of full pay for Dental Officers are as follows:—

	£ £
Surgeon Lieutenant (D)	377–462
Surgeon Lieutenant Commander (D) (promoted after six years' service)	556–687
Surgeon Commander (D) (promoted by selection to fill vacancies in Establishment)	730–933
Surgeon Captain (D) (promoted by selection to fill vacancy in Establishment).. ..	1073–1329

The Regulations regarding Pension and Withdrawal Gratuities are the same as for Medical Officers in the corresponding Ranks.

HONORARY APPOINTMENTS TO THE KING.

The King has approved of the appointment of Lieut.-Colonel R. McCarrison, C.I.E., and Lieut.-Colonel W. H. Leonard to be honorary physicians to His Majesty, with the brevet rank of Colonel, in succession to Colonel C. R. Bakhle and Major-General A. A. Gibbs, retired; and the appointment of Lieut.-Colonel G. D. Franklin, C.I.E., O.B.E., to be honorary surgeon to His Majesty, with the brevet rank of Colonel, in succession to Colonel R. W. Knox, D.S.O., retired.

RESTRICTED LEAVE OWING TO SMALL-POX.

Owing to the presence of small-pox in the area, restrictions have been placed on the granting of leave at Brechin (Forfarshire) and Kingston-upon-Hull. There are now two districts scheduled in London (St. Marylebone and Wandsworth) and 53 outside.

ROYAL NAVAL MEDICAL SERVICE.

To be Surg. Lts.: J. G. Ollerenshaw, T. W. Froggatt A. N. Forsyth, C. H. Birt, A. J. Burden, D. R. F. Bertram and D. L. Pow.

Sub-Lts. to be Lts.: B. E. W. Logan, J. B. G. Tem K. H. Fraser, and H. C. Browne.

The following appts. are notified: Surg. Comdrs. C. F Sankey to *Barham*, and to *Warspite* (on transfer of fla and G. H. Hayes to *Ramillies*. Surg. Lts. J. Johnstor *Resolution*; L. P. Spero to *Dahlia*; H. J. McCann *Pembroke* for R.N. Barracks, Chatham, temp. sup V. G. Horan to *Heliotrope*; C. B. Fox to *Rodn* D. R. Campbell to *Iroquois*; I. J. Corbett to *Victory* R.N. Barracks, Portsmouth, temp.; and S. J. Savage *Pembroke* for R. N. Hospital, Chatham, temp.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. W. J. Payne and Surg. Lt. R. Stubbs to *Victory*, for R.N. Hospl., Haslar, for training.

ROYAL ARMY MEDICAL CORPS.

Maj. G. S. Parkinson retires on retd. pay and is gra the rank of Lt.-Col.

Maj. J. St. A. Maughan to be Lt.-Col., vice Lt.-Col. W Croly to retd. pay.

Capt. J. Vallance, Reg. Army Res. of Off., relinquishes appt. and resumes the rank of Maj.

Capts. R. H. C. Pryn and T. L. Henderson to be Ma

Capt. B. C. W. Pasco, late R.A.M.C., to be temp. Ca and temporarily relinquishes the rank of Capt.

Lts. (on prob.) W. R. C. Spicer, J. H. Anderson, T. F Woods, S. M. Burrows, G. T. L. Archer, M. R. Bu P. J. L. Capon, D. R. W. Burbury, K. McNeill, P. Dw P. W. A. Agnew, and J. W. Kendall are confirmed in t rank.

The undermentioned Lts. from the secd. list are re to the estab.: L. R. S. MacFarlane and W. F. Lane.

To be Lts. on prob.: Lt. A. T. H. Marsden, from R.A. (T.A.); 2nd Lt. L. R. H. Keatinge, from T.A. Res. of Gen. List; Temp. Lt. G. L. Grieve, and relinquishes temp. rank of Lt.

The undermentioned Lts. on prob. are secd.: F. W N. J. Nicholson, H. W. Daukes, and D. C. MacE. Macpher

ARMY DENTAL CORPS.

Capt. A. Gibson to be Maj.

Temp. Lt. H. Quinlan, Dental Surg., Gen. List, to be

ARMY RESERVE OF OFFICERS.

Cols. J. W. Leake and F. Ashe, having attained the limit of liability to recall, cease to belong to the Res. of

Maj. J. H. Barbour, having attained the age limi liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. E. T. Burke resigns his commn. and is granted rank of Lt.-Col.

Capt. J. V. Bates to be Lt.-Col. and to comd. the 1 (Home Counties) Fd. Amb., vice Lt.-Col. P. J. Gaffi vacated.

Capt. E. B. Hinde resigns his commn. and is granted rank of Maj.

2nd Lt. W. E. Hayes (late R.E.) to be Lt.

Supernumerary for service with O.T.C.: Capt. H Malcolm to be Maj.

ROYAL AIR FORCE.

Flight Lt. A. F. Cook is seconded for duty with Transjordan Frontier Force.

Flying Officer E. A. Rice is promoted to the ran Flight Lt.

Flight Lt. C. Sempill de Segundo relinquishes temporary commission on completion of service.

RESERVE OF AIR FORCE OFFICERS.

Squadron Leader E. P. Punch relinquishes his commi on completion of service.

INDIAN MEDICAL SERVICE.

Lt.-Col. T. Hunter retires.

GUY'S HOSPITAL.—The annual report upon work of Thomas Guy's foundation shows that in 1927 1 in-patients were admitted, an increase of 1000 over previous year. There were 122,446 new out-patients made 537,676 attendances; they cost 7*s.* each. in-patients cost £11 19*s.* 2*d.* each. The total income £164,000 and the expenditure £172,000; the accumu adverse balance of expenditure over income now ex £100,000, and an appeal is being made for £500,000 fo re-endowment of the hospital.

The Clinical Interpretation of Aids to Diagnosis.

eries of Special Articles contributed by Invitation.

I.

E WIDAL OR AGGLUTINATION REACTION IN THE DIAGNOSIS OF INFECTIONS UE TO ENTERIC GROUP OF MICRO-ORGANISMS.

By A. B. Rosher, M.R.C.S., D.P.H.,
RECTOR OF THE CHARING CROSS HOSPITAL INSTITUTE OF PATHOLOGY.

r order to estimate the value and limitations of agglutination reaction in the diagnosis of these ctions it is necessary to have some knowledge of modern technique employed for the test and to eciate the behaviour of agglutinins under certain litions.

Macroscopic Method.

ne macroscopic technique is nowadays almost riably used in preference to the microscopic iod. By this means the end-point of agglutination be obtained more accurately, and there is no chance ne laboratory worker being infected, since dead lli are used instead of living ones. The test is sensitive when this method is employed, and it no means uncommon to demonstrate agglutinins serum after it has been diluted 1/40,000 times. highest dilution of patient's serum still having power of agglutinating the bacilli is commonly d the "agglutinin titre." The criterion of nosis by the old-fashioned microscopic method an agglutinin titre in the neighbourhood of), whereas agglutination to this titre could not sself be regarded as diagnostic when the macro- ic technique is employed.

is customary to put the patient's serum up nst *B. typhosus*, *B. paratyphosus* A, B, and C, nteritidis Gaertner, and *B. aertrycke*. The vast rity of infections in this country are due to *phosus* and *B. paratyphosus* B.

enteritidis Gaertner and *B. aertrycke* are the nisms usually associated with food poisoning the symptoms of acute gastro-enteritis pre- nate, but on rare occasions are stated to give o febrile conditions resembling enteric in some cts.[1 2 3]

Collection of Blood.

re blood is required when the macroscopic test ployed, and this represents the only disadvantage e method. Not less than 2 or 3 c.cm. of blood are able, and whatever method of collection is oyed it is advisable that the tube or syringe which it is collected should be perfectly dry free from any chemical substance, otherwise the l is likely to become hæmolysed and useless for est.

a syringe be used and sterilised by boiling or alcohol and ether, it is essential to wash it out sterile saline before withdrawing the blood. blood is usually obtained either (1) by pricking nger or thumb with a No. 2 triangular-pointed e, a small indiarubber tourniquet having been ously applied to the base of the digit; or (2) by ing a hollow needle into the median basilic vein collecting the blood direct into a syringe or into t-tube.

wever, by using a Behring venule ample tity of blood can be obtained quite easily, and rocedure is practically painless. Special venules supplied for the diagnosis of enteric whereby l is drawn from the patient for the agglutination nd blood culture simultaneously, thereby saving atient the inconvenience of being punctured . Since the blood goes straight into the culture m the risk of contamination is eliminated.

Technique.

Briefly, the technique is as follows:—

The blood is allowed to clot and, after centrifuging, the serum is drawn off. Various dilutions—e.g., 1/10, 1/20, 1/40, &c., to 1/1280—of the serum in normal saline are made in a series of test-tubes. The dilutions are made with graduated pipettes or by using Dreyer's dropping pipettes.[4]

Seven Dreyer's agglutination tubes[4] are then placed in a rack and 0·5 c.cm. of an emulsion of dead typhoid bacilli is put in each tube. (These emulsions are made by growing the organisms in bouillon for 24 hours, after which a small quantity of formalin is added to kill them. The emulsion is then standardised to contain so many organisms per c.cm., and if kept cool and in the dark can be used for some months.) Half a cubic centimetre of the 1/10 dilution of the patient's serum is now transferred to the first agglutination tube, and the same amount of the 1/20 to the second tube, and so on with all the dilutions. We now have a series of seven tubes containing a range of dilutions from 1/20 to 1/1280 of the patient's serum mixed with typhoid emulsion; each tube contains 1 c.cm. of fluid. The patient's serum is then put up against emulsions of paratyphoid bacilli in exactly the same manner, seven tubes being devoted to each organism. The rack is then placed in a water-bath at 55° C. for two hours or so. Agglutination usually commences in 10 to 15 minutes, and can easily be observed with the naked eye against a dark background. The contents of tubes showing no agglutination appear slightly cloudy, owing to the millions of bacilli in suspension, but when agglutination has occurred they become aggregated into large clumps which fall to the bottom of the tubes, resembling a precipitate, and the supernatant fluid is quite clear. The tubes are inspected occasionally, and if any organism is agglutinated in all dilutions up to 1/1280 further dilutions are put up—e.g., 1/2560, 1/5120, 1/10,240, &c.—so that the end-point of agglutination can be established.

Occurrence of Agglutinins in the Serum of Apparently Normal People.

If we test blood from these members of the population who have not been inoculated with T.A.B. vaccine and give no history of having had enteric against this group of organisms, we find that about 4 per cent. of them agglutinate *B. typhosus*, *B. paratyphosus* B and C, and *B. enteritidis* Gaertner, whereas about 10 per cent. react with *B. aertrycke* (Mutton).[5] The reason for this agglutination is unexplained, but it is possible that the people have passed through unrecognised infections with these organisms or closely allied ones. (A point in favour of this theory is the absence of people who can agglutinate *B. paratyphosus* A, for infections with this organism are extremely rare in the British Isles.) Some of these people may be carriers, for it is well recognised that the serum of the majority of carriers contains agglutinins; not enough cases have been investigated for any definite conclusions to be formed. The majority of sera give low agglutination titres, such as 1/20, 1/40, 1/80, but occasionally one finds a serum that will agglutinate when diluted as much as 1/640 times. As far as one can ascertain, these titres remain constant and do not fluctuate over a period of weeks.

Behaviour of Agglutinins as a Result of Infection.

Agglutinins do not appear in the blood until the end of the first week of disease, and therefore it is useless to expect any immediate diagnostic information from the reaction before this. Nevertheless, it is very important to perform the test during the first few days, since a negative result is invaluable in assessing the significance of results obtained later in the disease, especially in cases which only give low agglutinin titres throughout. However, it is during the early days that the chances of isolating the causative organism from the blood, fæces, &c., are best, and therefore cultures should also be made.

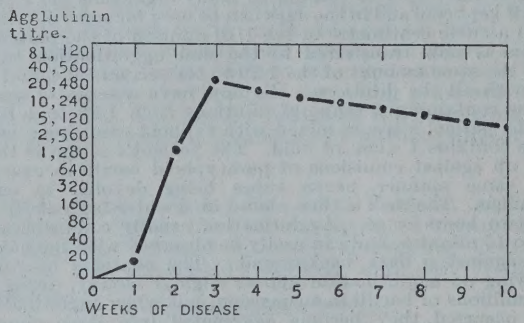
The agglutinins increase rapidly in intensity, reaching a maximum towards the end of the third week and then start to fall gradually (see Chart 1). They fade away over a period of months, but may last for years. There is a considerable variation in the amount of agglutinin production in different cases. Thus sometimes the highest agglutinin titre reached may be more than 1/40,000, whereas in other cases the maximum titre may be on the 1/100 mark. The

latter event is unusual, and this is fortunate, since in these cases a diagnosis cannot be established on a single test, and repeated tests have to be performed (see below).

Behaviour of Aggutinins Resulting from Protective Inoculation.

As a result of inoculating a person with a vaccine prepared from typhoid and paratyphoid bacilli (T.A.B.), agglutinins to these various organisms appear

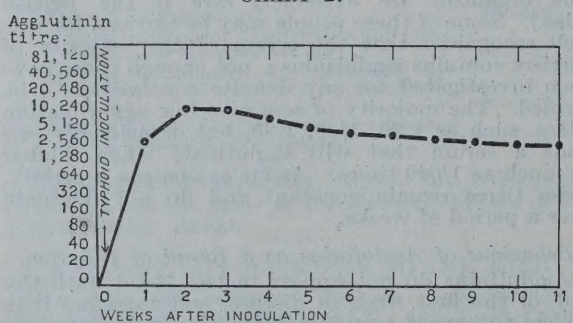
CHART 1.



Showing the behaviour of agglutinins during an infection. Note the rapid rise in the second and third weeks.

in the serum (see Chart 2). They reach their maximum after two or three weeks, and then usually fall to a level round about the 1/500 mark; here they remain for many years, and in some cases no doubt for a lifetime. The tendency is for them to get less as time goes on, but the process is so gradual that when tests are made once a week for several weeks and no change in agglutinin titre can be demonstrated. There is considerable evidence[6] to show that nothing will cause any fluctuation of the agglutinin titre at this stage unless a person becomes infected with one of the enteric group of bacilli. In the event of this happening the agglutinins for the infecting organism rapidly rise and reach a maximum towards the end of the third week. Then they gradually fall, and in all probability become stationary once again on a level somewhat higher than they were before the

CHART 2.



Showing the behaviour of agglutinins resulting from inoculation.

infection took place. Thus the behaviour of the agglutinins in a person suffering from enteric infection is the same whether the person has been inoculated or not, except that in the inoculated they start from a definite level (see Chart 3), whereas in the uninoculated they start from zero.

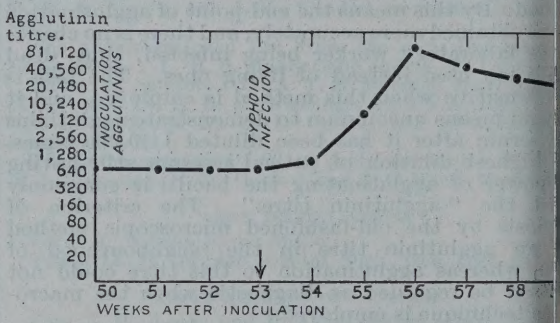
Diagnosis of Infection Agglutinins.

If we are confronted with a serum which agglutinates one or more of these organisms it should be clear from the above remarks that the agglutination may be due to: (1) "normal" agglutinins; (2) infection agglutinins; (3) inoculation agglutinins; (4) a combination of the above. It then becomes necessary to distinguish infection agglutinins from the remainder. One can usually rule out inoculation agglutinins by questioning the patient; but, apart from this, t fact that a serum agglutinates the three organisn *B. typhosus*, *B. paratyphosus* A and B, is usual sufficient indication that inoculation has taken pla

The essentials for diagnosis *in the uninoculated* mu then be considered. A titre of 1/1000 must always regarded as strongly suspicious, and if it is consid ably higher than this a presumptive diagnosis infection can be made. It must be remembere however, that occasionally titres as high as this a not registered even when the agglutination is at maximum at the end of the third week. In the cases it is necessary to perform two or even three te with an interval of three or four days between then if there is any appreciable increase or decrease titre (according to the stage of the disease) a diagno of infection is justified. The occurrence of these cas makes it of the utmost importance to test the blo in the first few days of disease, for if it is then negati and a few days later agglutinins appear, a diagno of infection is justified, even if the titre of the seco test is only on the 1/20 or 1/40 mark.

The diagnosis by means of repeated tests is fai easy during the first three weeks of disease, since t rise in agglutinins is rapid; but after this period

CHART 3.



Showing the behaviour of the agglutinins in the case of inoculated person becoming infected. This chart gives idea of what would happen to the agglutinins if a pe became infected with *B. typhosus* 53 weeks after be inoculated.

is less satisfactory, and may be a lengthy procedu for the fall in agglutinins may be very gradual.

In the inoculated a single test by itself is of v little value, and it is essential to perform, at any ra two tests with an interval of three or four da between them in order to demonstrate the fluctuat in titre characteristic of infection. As has b noted above, after inoculation agglutinins have sett down to a steady level no change can be detec in them over a short period unless the patient becor infected with organisms of the enteric group.

Value of the Test.

The agglutination reaction thus has a defi value in the diagnosis of these infections, and may even more useful in the future. The work of E. W and A. Felix[7] and others has shown that typhoid a paratyphoid bacilli contain two kinds of antig which differ in their resistance to heat and to cert chemical agents. These, for reasons which do concern us here, have come to be called the H an antigens. It has been claimed by Felix that agg tinins acting on the O antigens appear only as a re of infection, and that, by using an emulsion contain O antigens, it is possible to arrive at a diagnosis the result of a single agglutination test even in inoculated individual. Burnet[8] has recorded sim results. If these observations are widely confirm by future investigations they will clearly make important advance in the diagnostic application of test.

The great value of the agglutination test, compa with other methods of diagnosis of these infecti is the fact that agglutinins after the first week so are almost always present, and therefore sho

capable of demonstration, whereas the causative anisms can only be isolated from the blood in n 70 to 80 per cent. of cases. and from the fæces bout 50 per cent. A blood culture when positive ne most satisfactory means of diagnosis, because gives conclusive proof of infection, while the utination reaction only gives indirect proof. The ence of typhoid or paratyphoid bacilli in the fæces rine means that the patient is either a carrier or uffering from an active infection with these anisms, and it is permissible to assume an active ction if the symptoms are sufficiently suggestive. ach method of diagnosis, therefore, has its limita-s, and in order to obtain the best results it is ntial on encountering a suspected case: (1) to te cultures from the blood, fæces, urine, and um (if present); (2) to perform an agglutina- reaction; (3) to perform a leucocyte count. se three investigations should be carried out tever the stage of disease. The leucocyte count valuable because it takes very little time to perform, if a leucopenia is present one can usually rule most of the infections likely to resemble enteric cally, with the exception of influenza. The lt of the agglutination reaction should be inable in two or three hours, but isolation and tification of the causative organism may take e days.

The Diagnosis of Bacterial Food Poisoning.

ne agglutination test also has some value in the nosis of bacterial food poisoning. These infections isually due to various types of *B. aertrycke* and to *nteritidis* Gaertner. Blood cultures are of very value, and the diagnosis is usually made by ting the causative organism from the fæces. The utination reaction affords valuable support, but s to be interpreted with care, owing to the rmal" people who agglutinate these organisms; nermore, people who have been inoculated with B. frequently agglutinate *B. aertrycke* and *B. itidis* Gaertner, owing to the close serological ionship of members of this group of bacilli. owever, this non-specific or group agglutination gard *B. aertrycke* can be avoided by using type lsions, as shown by Andrewes.[9]

Conclusion.

conclusion, attention must be drawn to the rtance of supplying the bacteriologist with brief ils of the case under investigation, especially ding the duration of the disease, inoculation, so forth. Neglect to do this is, no doubt, nsible for the complaints sometimes made by titioners of incomprehensible laboratory reports. successful diagnosis of enteric can only be accom-ed by close coöperation between the clinician the laboratory worker.

ARIE CÉLESTE SAMARITAN SOCIETY.—During the six months of the present year this society, which was lished to help patients of the London Hospital, ted 6739 persons, an increase of 402 as compared with orresponding period of last year. Surgical appliances been supplied to 2625 patients, and 1323 have been to the sea or the country.

REASURER OF RADCLIFFE INFIRMARY.—The Rev. Cronshaw, upon his appointment as Principal of St. nd Hall, has resigned the treasurership of the Radcliffe nary, which he has held for the last 18 years. During eriod the hospital, by reason of his energy and activity, en greatly improved and its usefulness widely extended. cognition of his services Mr. Cronshaw has been made e-president.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT CARDIFF.

(*Continued from p. 351.*)

SECTION OF MEDICAL SOCIOLOGY.

THE FALLING BIRTH-RATE.

Prof. W. J. ROBERTS (University College, South Wales), in opening the subject from

The Economic Aspect,

referred to the writings of Malthus, and stated that nowadays no simple and definite theory as to the law of population held the field. Official statistical data threw no light on the means by which the reduction of births was secured. Apprehensions had found expression with respect to the decline of the French population, and in the U.S.A. as to the higher birth-rate among unassimilated immigrants when compared with the pure Americans. It was also believed that in Britain birth control prevailed more widely among the relatively better situated. Sir Arthur Newsholme had dealt with the thesis that it was not a matter of indifference as to which races peopled the unfilled portions of the world and took the preponderant share in shaping the destinies of mankind. He had also referred to the fact that in the earlier years of certain industries each child was his parents' savings bank, and that now the child was a less profitable asset than in the past. Economic inquiry tended to destroy utterly the impression that the people of this island were divided by social circumstances into breeds, some of which were fitted by origin and nature to bear rule over the others. The economist wished to have many questions answered, both by the biologist and the social investigator. For example: Are the "comfortable classes" the result of biological excellence? Are the classes which exhibit aptitude for leadership and command in danger of perishing if their stock is not continued? The obstacles to the growth of population and the causes of misery and restricted livelihood in the mass of the people are not due to any law of population or to the niggardliness of nature. Neither our own little planet nor our own little island was overcrowded. The causes were rather to be sought in habits and institutions whose origin and purpose was mastery, privilege, and monopoly. The continuous unfolding of productive capacity depended on the prevalence of justice throughout the whole economic community. He did not pretend to any social or medical knowledge, but as an economist would like answers to many questions. How did gambling or the desire to get rich quickly operate? What was the effect of outdoor games and a life of pleasure on fertility? What was the effect of the conventions of each social class on its individuals? Did people follow medical advice on these subjects? And did people really know why they acted in a certain way? The term "overcrowding" was used very loosely, the standards adopted were rough, and halving of the population did not necessarily diminish overcrowding, even if the number of houses remained the same. Ordinary economic explanations were of no avail for this problem, and far more detailed inquiry and intelligent questioning of all classes by people who could put themselves in other peoples' places was needed.

The Biological Aspect.

Prof. F. A. E. CREW (Animal Breeding Research Department, University of Edinburgh) said the birth-rate of this country had fallen and was still falling, and that this was a matter of grave concern to those who chose to envisage the overwhelming of our prized culture by hordes of barbarians of this or that particular hue, but all equally and amazingly fertile. To the biologist, however, there was nothing remarkable and nothing necessarily ominous in this decline. If the conclusions which had emerged from the work of Pearl, Elton and others had been known when the birth-rate was soaring, the present fall would have

been foreseen and accurately predicted. The growth of all living things, whether pumpkins or peoples, followed the law enunciated by Pearl—namely, that the population at first grows slowly, gradually gains impetus, and then grows rapidly. Rapid growth is succeeded by a slowing off which ends in no growth at all. Increasing density led ultimately to complete saturation, and reduction in population was achieved by removing the surplus or by reducing the rate of growth. The first method of reduction was the catastrophic and was exemplified in rabbits, mice, and human populations, the catastrophic instruments being war, pestilence, and famine. The second or gradual method of reduction was revealed in the work of Pearl on Drosophila, the primary factor being a fall of fecundity and fertility with increasing density. Among pigs under similar conditions there was noticed a reduction in the size of the litters. Group biology was a new study. Experiments with animals did not necessarily apply to human beings. Man could adapt himself to a changed environment, and every advance in knowledge which enabled him to derive from his environment things conducive to his material welfare increased the potentialities for population growth in a given area. A rising birth-rate heralded an extension of the conquest of man of his environment, while a falling birth-rate was an indication that mankind was temporarily imprisoned. The birth-rate was now falling because this was the end of a population growth-cycle. A new growth-cycle would be initiated and the birth-rate would rise when those factors which were at present overriding the inherent tendency to increase were recognised or removed.

Fecundity was affected by inborn and environmental factors and different races, stocks, and individuals were distinguished, one from the other, by true-breeding differences in fecundity. In the human subject the tendency to multiple births was faithfully transmitted through both male and females. The time of onset of puberty and of the climacteric and also longevity were true-breeding characters. It was possible that in the past the inherently longer-lived had contributed disproportionately to the population, and that under modern conditions the shorter-lived lived longer and transmitted to their progeny a lowered fecundity. This would be a reasonable explanation of a lowered birth-rate if it could be shown that there was a high correlation between longevity and high reproductive rate. This country was now relatively overcrowded. Lack of houses was an indication of a relative regional over-population. If the builders failed to keep pace with the babies the birth-rate would fall. It was not known how density provoked its results, but the work of Pitt-Rivers suggested that sheer discouragement was enough to destroy a people.

What effect had the conflict of cultures? The birth-rate of the vanishing peoples of the South Seas was steadily falling, apparently because these peoples were discontented and discouraged, and consequently dying out. Did the arrival of an immigrant Irishman in Glasgow prevent a Scottish baby from being born? There must be joyousness, eagerness, roominess for potential parents or else the babies would not come. The birds, when they mated, built nests, but for human lovers the tenements were built by those who were ignorant of the relation which existed between population density and the reproductive rate. The sex ratio could not as yet be controlled. The fact that many women could not become mothers could not explain the falling birth-rate. A high marriage-rate associated with a low per-reproductive-woman birth-rate could yield the same reproductive rate as a low marriage-rate associated with a high per-reproductive-woman birth-rate. Few marriages and larger families might yield a high reproductive rate with less variety among the offspring and surely variety was to be desired. The present low birth-rate was in part due to sterile marriages. Two individuals mutually sterile might be fruitful in other matings. Possibly recent social and economic developments had encouraged the survival of stocks, which were relatively infecund or which reacted more readily to the disharmonies of industrialism. The peak of sex activity was at about 29 in the male and the woma reproductive power dropped shortly after 30.

Prosperity implied plentiful food and comfo and therefore a lower death-rate and a rising bi rate, and an unequally distributed prosperity mi create differential fertility among the social gra If a large section of the community were relativ unsuccessful and left with no other modes of nerv release than excessive drinking and sexual o indulgence, there would be a higher reproductive r in this section than among the community as a wh Social advancement implied a lower reproductive r as those who experienced it were presented with n varied modes of self-expression and self-indulge Unless it could be shown that the methods adopted birth control were effectual, it could not be accep that birth control was largely responsible for a fal the birth-rate. The fall in the birth-rate had been gentle; it had proceeded with evolutionary steadi and had been universal. This suggested the expres of some biological factor. He doubted if b control had affected the crude birth-rate, but s gested that it might have slammed the doors suburban houses to open those of a slum. The probl thus, was to determine the biological worthines the social grades. What was fitness? There was reason to suppose that it was linked with high-gr fecundity. The elephant and the earwig were fit had quite different reproductive rates. Was the hu standard of fitness to be good physique, good br and low-grade fecundity? If so, this ideal coul found abundantly among all social grades. suggestion that the relatively unfit were n abundant among the socially submerged was necessarily true. It was easier for a good ma climb out of the gutter than for a biologically unwo scion of an established family to descend because latter was buoyed up by his associates. If b control had played a part, it would have been for humanity if it had been the only responsible ag used intelligently by a people, who knew what t did and why they did it. At present it seemed t the methods adopted were too uncertain to allo any policy being based upon them. In his conclu remarks Prof. Crew said he had tried to be provoca and had incautiously stepped from the solid gro of fact to the uncertain terrain of opinion, but tha set no great store on his opinions and would not n exchanging them for better ones.

The Medical Aspect.

Sir THOMAS HORDER thought the falling birth- was a matter outside the province of medical r They must have more facts from the biologist and economist. Sex incompatibility was a mystery and laws of reproduction were inscrutable. The prolo tion of life was a small matter, but the saving of life the improvement of health were great matters. age was on the increase. We had a lower birth- and would ultimately have a higher death-rate. visitor from another planet would be amused to us worrying over a falling birth-rate when so rece we were complaining of the rapid increase of the p lation. He did not think the differentiation of birth-rate resulting in poorer quality came within doctor's sphere. The husband and wife usu consulted the doctor when they had made up t own minds on this matter. If the doctor was to e this field he must be taught very differently. If were to breed from superior parents Governm would have to fix a minimum of, say, three chil with a double minimum for very superior par and subsidies would have to be provided from t who did not comply with the minimum. Sociolo must arouse interest in eugenics before the do could take a hand. The profession had stood owing to want of data.

Lady BARRETT (London) dissented from Sir Tho Horder's view that this was not a matter for medical profession. She gave many statistics regard to the fall in the birth-rate, and also

istics with regard to the fertility of women accord- to their age at marriage, derived from the experi- e of Scotland in 1855. She concluded that 25 was best age for marriage. If the true facts were wn with regard to the chances of immediate ception many more young couples would begin r married life in a natural manner. If there was ger to the mother from childbearing the family tor was the best person to advise. Medical lents should be taught all that was known on this ject in order that they might give suitable advice heir patients. Unless the medical profession took nterest in this problem and spoke out there was a it danger of race deterioration as the result of the erential birth-rate.

Discussion.

r. WILLIAM COLLIER (Oxford) said that for 40 years h control had been practised in the professional ses, and they had no right to deny information he working classes. If medical science set itself mprove methods they would be improved. They t not sit on a hedge because the subject was asteful. Panel practitioners had no time to advise, should refer their patients to good clinics. A -class birth control clinic had been inaugurated ambridge under medical direction, but in spite of support of the Oxford Medical Society they had with much opposition and had been unable to blish one at Oxford.

r. LETITIA FAIRFIELD said that the doctor's ning gave him no locus standi. More biological were wanted. Causes of the falling birth-rate voluntary and involuntary, but the involuntary es were not really natural laws. Joy in life luced the desire for children, and regard for the th of the mother produced a reasonable form of control. She did not think they need worry about falling birth-rate.

r. BINNIE DUNLOP (London) said there was a real and for information on this subject, and caused amusement by his suggestion that there should no more children till all the adults had been factorily provided for.

rs. NEVILLE ROLFE dealt with the effect of vation. The birth-rate in Italy had declined, it remained high in China and among the Jews, religious motives. The necessary fillip to the -rate referred to by Prof. Crew could readily be lied by emigration. We had areas crying out for e population, and we ought to emigrate good . Under the 1922 Act local authorities could , equip, and emigrate, but they only emigrated . They should go in for group emigration with oken British family traditions. Local authorities ld send out girls and boys in equal numbers. gration was the best means of stemming the ne in the birth-rate.

. N. E. WATERFIELD (Banbury), from his experi- as a general practitioner, thought parents asked nd acted on the doctor's advice.

Reply.

of. ROBERTS asked if social conditions were just, suggested that many of these problems would be d if the ideals of the community were raised.

of. CREW agreed with the importance of the vating force, and said a new religion was needed. grants should be successful people at the repro- ive age.

SECTION OF PREVENTIVE MEDICINE.

CONTROL OF INFECTIOUS DISEASE.

he value of present methods of controlling infec- diseases was discussed under the presidency of E. COLSTON WILLIAMS (Cardiff).

Small-pox.

. L. J. RAJCHMANN (Director of the Health nisation, League of Nations) surveyed the viour of small-pox in the various countries of world. Events at Rio de Janeiro in 1926, and in ria in 1926 and 1927, showed, he said, that severe outbreaks of small-pox had not ceased to occur. During 1927 a large area of Europe was free from small-pox; since 1919 there had been a huge drop in its prevalence in Rumania and Soviet Russia; in each case notification had improved. In the Far East there had also been a drop. During the late war England and France remained clear; in Germany in 1917 the barriers against small-pox broke down, and this was much more the case in Austria, Hungary, and Italy. The crest was reached in 1920; after that came the decline. In 1927 there were no cases in 15 European countries, and very few in 15 others. In France, in spite of efficient vaccination, the prevalence was said to be kept up by imported cases. In France, Germany, and Italy the disease was of the classical type. In Switzerland a mild type of small-pox, similar to that in England at present, was prevalent from 1921 to 1926, but has now entirely disappeared. The case mortality of small-pox varied greatly not only between one country and another, but also from year to year. Italian statistics were particularly interesting, and showed that the severity of the disease and its case fatality underwent cyclical variation, roughly in seven-year periods. There was no evidence that the classical type was being replaced anywhere by the mild type. The case fatality in England from the mild type was now between 0·2 and 0·3 per cent. In Germany during 1919 to 1922 the case fatality varied from 12 to 16 per cent. In France the case fatality was between 28 and 29 per cent. from 1919 to 1921. In Rumania the figure of 28 per cent. for 1919 became 12 per cent. in 1923. In extra-European countries the figure varied from 10 to 30 per cent. In India and Korea during 1926 and 1927 it was about 25 per cent. In Java the figure 26 per cent. in 1918 fell to 12 per cent. in 1923, and was only 2·7 per cent. in 1927—a very low figure for a tropical country. Figures for Africa show that a low case fatality of 2 to 10 is not uncommon, but that severe epidemics with a 30 per cent. mortality do occur. In European countries there are no statistics for trustworthy death-rates according to age-periods, but the Italian statistics show a marked excess of the female rate at ages from 20 to 44. Owing to the influence of the vaccinal condition it is difficult to determine whether fluctuations due to any other cause occur. The seasonal distribution of the mild and severe types did not differ materially.

Dr. J. MIDDLETON MARTIN (Gloucestershire) pointed out that mild small-pox was no new thing, and that in the past inoculation had come into fashion when the type of the disease was mild. The tendency to regard infection as being spread by persons rather than by infected articles was growing, and belief in aerial spread of infection was practically given up. Their main business was to prevent case to case infection. Their principal difficulty was the detection of mild small-pox. Small-pox was not a dual disease but one disease of varying severity. The percentage of vaccinated school-children in Gloucestershire had dropped from 70 to 25, and their present means of control depended upon quickness in detection.

Dr. T. EUSTACE HILL (Durham County) had no doubt that the mild disease was true small-pox. They had had 12,634 cases from 1922 to May 31st, 1928, with 34 deaths. Of the 34 deaths, 6 occurred under 1 month of age, 4 under 3 months, 2 at 1–2 years, 3 at 2–5 years, 3 at 5–15 years, 5 at 15–25 years, 1 at 25–45 years, 5 at 45–65 years, and 5 at 65 and upwards. The cost to the county had been £120,000, but nevertheless he thought they ought to continue isolating the cases as they could not trust to the mild disease breeding true. Discussing methods of control, he argued that it was impossible to make vaccination compulsory at present. He paid tribute to the valuable work done by the port sanitary authorities. Wilful concealment and failure to diagnose impeded prompt notification. All medical officers of health should make themselves expert in diagnosis, and county medical officers of health should act as consultants. The supervision of contacts was not always efficient. They had successfully pooled

the hospital accommodation in Durham County, and they had not found that overcrowding the hospitals had caused septic cases. "Return" cases had occurred owing to the demand for hospital accommodation. Disinfection was still advisable. He had had no experience of the supposed relation between encephalitis and vaccination. (Dr. Rajchmann in his opening remarks mentioned that a Special Commission of the League of Nations was at present investigating this matter.)

Dr. R. P. GARROW (Chesterfield) explained the continuous prevalence of small-pox in this country by the extraordinary mildness of the cases. Even confluent cases were not ill. The refusers of vaccination were of the lowest class. He suggested the omission of hospital isolation and the treatment of cases at home with vaccination of the contacts. At the present time in his district it was considered preferable to have a pleasant three weeks in hospital with small-pox than to suffer from vaccination at home. He believed that the mild type was a separate disease, and that even if it did change its type the occurrence of a few deaths would stimulate the demand for vaccination.

Dr. R. BRUCE LOW (Ministry of Health) thought the mild type was not so trivial, and was apt to be fatal to the newly born; he urged the need for stamping out the disease, and showed that the present failure was caused by the well-tried preventive methods not being properly enforced. He suggested that owing to the mildness of the disease the general practitioner regarded it with scorn; the cases were not promptly removed, the contacts were not followed up carefully, and there was no propagandism with regard to vaccination. He suggested that the mild type was more easily stamped out because it was less infectious, and that supervision of contacts should be extended from 16 to 20 days because the appearance of the rash was frequently delayed. To show that the mild type was no new thing he quoted from the letter of a doctor in 1722: "one type of small-pox the nurse cannot kill and one type the doctor cannot cure."

Sir MALCOLM WATSON (Malaya) showed how small-pox had been stamped out in the Malay States by efficient vaccination, and suggested the advisability of postponing vaccination till after the first year of life.

Dr. A. E. BRINDLEY (Derby) emphasised the large amount of concealment of the disease which went on.

Prof. HAROLD KERR (Newcastle-on-Tyne) said that contacts dreaded vaccination more than the disease, and hoped that it would be possible to reduce the virulence of the lymph even if it shortened the period of immunity. His town gave compensation to those who were laid off work owing to vaccination. He mentioned the case of seven painters who were exposed to infection and vaccinated. Three were off work, one of them for 11 weeks, and received their wages all the time. He did not agree with Dr. Garrow's proposal to leave the cases at home. The medical officer of health of a neighbouring district had refused to believe that the disease was small-pox. As a result infection spread to Newcastle and the consuls arranged for ships to be taken to other ports. In any ordinary big town the mild type of the disease could be controlled without difficulty.

Dr. R. M. F. PICKEN (Cardiff) said that better-class persons were also refusing vaccination. It was impossible to get efficient vaccination and revaccination against this mild type of the disease. Stunts for the vaccination of the whole population would only make us a laughing stock.

Diphtheria and Scarlet Fever.

Dr. R. A. O'BRIEN gave many instances to show how outbreaks of diphtheria could be prevented and controlled in resident schools and among hospital staffs, and went on to discuss some of the failures to apply our present knowledge. If antitoxin were given in the first 24 hours of the disease there would be no deaths from diphtheria. Statistics from the U.S.A. and from the reports of British medical officers of health showed that there was much delay of parents in calling in the doctor, much delay of doctors in making a diagnosis, further delay in waiting for the examination of the swab, and that frequently in the end an ineffective dose was given. Recent work showed that out of a thousand Schick-negative cases 97 per cent. remained negative after periods varying from one to seven years. Immunised persons who became Schick-positive rapidly regained their negativity with a Schick test. Three doses at intervals of one week was still the best method administered, but it was possible to give the Schick test after the first immunisation dose simultaneously. Some persons became immune after the first dose and some after the second. Dr. O'Brien described the work which was going on for the purpose of improving the methods.

Dr. J. GRAHAM FORBES (London) described the progress which is being made in London and throughout the provinces in immunising the children at welfare centres and in the schools against diphtheria. Thirteen of the London boroughs have now provided such facilities, and some outside districts, such as Willesden and Tottenham. In addition to this, very satisfactory results had been obtained in many residential institutions and among the staffs of the M.A.B. hospitals. There was a considerable increase in this work during 1927 throughout the whole country.

Dr. B. A. I. PETERS (Bristol) described the very satisfactory results obtained in the immunisation of the hospital staffs of Bristol. They had found that the Schick test was not always reliable in the case of very virulent strains of diphtheria. They had now adopted for the hospital staffs immunisation without previous Schick testing. Their experience of immunisation against scarlet fever had also been satisfactory; he thought that all local authorities should adopt immunisation methods for their hospital staffs.

Dr. E. H. R. HARRIES (Birmingham) referred to the great value of surgical treatment of the naso-pharynx in reducing the number of "return" cases of scarlet fever and diphtheria. The examination of throat swabs as a method of testing the fitness of diphtheria patients for discharge was now being given up. Although scarlet fever was usually mild in the case of children it was not always so in the case of probationer nurses, and it was well worth while to protect them by immunisation. He said it was high time that more facilities were provided for the education of medical students in the fever hospitals. They should act as clinical clerks for, say, a month, instead of the present spasmodic visits. "Return" cases of scarlet fever could best be prevented by immunisation of the contacts in the home. In order to secure the success of these new methods it was very necessary to have the full coöperation of the general practitioners.

SECTION OF PUBLIC HEALTH.

THE TEACHING OF HYGIENE.

In opening this discussion, over which Dr. R. M. PICKEN (Cardiff) presided, Prof. W. W. JAMESON (London School of Hygiene) limited his remarks to the teaching of preventive medicine to medical students, and to the training of other members of the health services. General practitioners being the first rank of health workers every effort must be made to arouse the preventive outlook among medical students. In this teaching mere sanitary engineering need not fill a large place; lectures for medical students should not be regarded as lectures for experts for the use of experts. Although the syllabus was much too wide at present it failed to deal with the sociological aspect. In the training of sanitary inspectors he attached great importance to experience as craftsmen in one of the building trades. There was a danger that such craftsmen might be kept back by the demand for too high a standard of gen

cation. He thought there should be more than port of entry for health visitors, although he ued highly the training of a nurse. These should probationary, and the salaries of health visitors per should equal those of teachers in elementary ools. In the training of midwives a distinction uld be made between those who intend to practise those who are going to take up other health k. The principal midwifery schools should be rved for the former, who should also have district ning. For the latter a minor qualification, which ht be termed "obstetric nurse," would suffice. ses who underwent training in a fever hospital e in an unsatisfactory position. If general pitals accepted them subsequently they were ted as if their fever training had been of no unt. Every trained nurse should have some r training, and one year of her training might be oted to this purpose. Health education in the ols should be carried out by teachers of the right e, and not by doctors or school medical officers. teachers needed to be taught hygiene on more active and practical lines than at present. Many l authorities had not taken any interest in health cation. He referred with approval to a syllabus wn up by Dr. Brackenbury in 1904, when chair- n of the Hornsey Education Committee, which, n minor alterations, had been in use ever since. ally, they must get the general practitioner to an interest in the education of the public. As rds broadcasting, he would prefer four-minute dcasts on matters of special health interest at particular moment, to the present 15 minutes th talks.

r. H. B. BRACKENBURY (chairman of B.M.A. ncil) expressed himself in agreement with Dr. eson. The General Medical Council, he pointed has no direct power over the teaching bodies, it can prescribe curricula and inspect examina- s. It was impossible to coördinate the work of ting voluntary health education bodies, 100 in ber. He thought that schools and general titioners should be the most effective instruments ducation. By educating the children they re- ated the parents. Education in sexual matters ld only be given to older girls by head teachers pecially qualified teachers; it had been success- done on these lines in Hornsey. There had erto been no attempt to deal with these questions secondary schools. The question of mental ene had been neglected, and teachers needed uction how to deal with mentally unstable and able children. He had not much faith in the fits likely to accrue from public lectures or from ectures of insurance practitioners to their patients. would put first in importance the schools, second day by day advice given by practitioners, and l the work of the health visitors in the homes.

r. D. LLEWELYN WILLIAMS (Welsh Board of lth) believed that the panel doctors had done h good since 1913, and were in a position to do l research into the beginnings of disease. They t secure a preventive outlook all through the ical curriculum. Birmingham had instituted ires by panel doctors to their own patients, for h the insurance committee paid full fees. The ts were claimed to be good.

. BRACKENBURY intervened to say that the esentative Body was doing its best to encourage ation by practitioners. A new household maga- was about to appear, and the Council of the ciation had accepted the responsibility of supply- ne page on health matters. The articles would nsigned.

. OLIVE WHEELER (Professor of Education, iff) emphasised the importance of close coöpera- between medical and educational bodies. For teaching of hygiene in the secondary schools ified biologists were needed; at present there more females than males taking up biology g those trained. Some of the biological teaching must be practical—e.g., gardening. For the primary schools the teaching of hygiene is not living and imaginative enough; nature study should be correlated with hygiene and health practice. In their four years' course for teachers the fourth year was given up to the application of biology and other sciences. They also studied psychology and such questions as fatigue and development from a biological point of view. Practical teaching in physical exercises and the playing of healthy games was important. They had in Cardiff a "College adviser of games," who worked in close touch with the medical officer of health. It was too late to begin at the age of 5, and therefore nursery schools were needed for the teaching of habits.

Prof. HAROLD KERR (Newcastle-on-Tyne) thought much could be done to make the course of lectures in hygiene for medical students more interesting. He showed what a large amount of field work was included in the course given at Newcastle, and claimed that as a result the students who subsequently practised in the neighbourhood were his best supporters.

Mr. JAMES MACKENZIE (Secretary, Industrial Health Education Society) described how his society was getting in touch with workers in all occupations, and arranging medical lectures to such workers. The workers chose the subject, the medical officer of health helped to find the right lecturer, and "heckling" was encouraged. The workers were anxious for information about the many occupations inimical to health and life. In spite of huge expenditure on sick and medical benefits not a penny was spent on education under the Insurance Act.

Dr. ERNEST JONES (M.O.H., Cardiganshire) agreed that the teaching of hygiene had failed because the teachers had no knowledge of the sciences on which it was founded. Health knowledge would be a better name for the subject. He described the methods of teaching biology and physiology and their application to the students at Aberystwyth College. His suggestion that the clergy would benefit by a course of biology aroused applause. There was too much psychology and too little biology; they needed more science and less classics.

Mr. CREW (Sec., Central Health Education Council) favoured education by panel doctors. Ordinary public lectures did not reach the right people, and his society's experience of lectures by panel doctors was not very good. His society arranged successful medical lectures in the schools, and for the explanation of health films.

Mr. H. S. BOMPAS (Sec., Dental Board Health Campaigns) described what the Board did in the matter of organising dental lectures and supplying first-class apparatus free of charge. He found that local authorities sometimes had good schemes only on paper, and that teachers and health visitors knew the requirements of the district best. Some education committees had little enthusiasm. The Dental Board's films had been shown all over Northern Ireland, but they were not allowed in Scotland.

Prof. F. E. WYNNE pointed out that the public health lecturer could not choose the subjects which he thought best because he had to fit his students for an examination conducted by other examiners.

Dr. A. G. ROBB (Belfast Fever Hospitals) thought every nurse should spend some portion of her training in a fever hospital.

Dr. CARSTAIRS DOUGLAS (Anderson College, Glasgow) agreed that sanitary engineering figured too largely in the public health course.

Dr. C. F. L. LEIPOLDT (Cape Town) pointed out that there was no teaching with regard to the normal child in the medical curriculum, and that the qualified medical man had to learn by experience in the schools.

Dr. LETITIA FAIRFIELD urged that teaching should be practical, and Mrs. NEVILLE ROLFE drew attention to the failure to supply health education for the three million adolescents of the country.

SECTION OF THERAPEUTICS.

Treatment of Gastric Diseases.

Dr. A. F. Hurst (New Lodge Clinic) opened a discussion on recent advances in treatment, remarking that he was himself unwilling to diagnose gastric or duodenal ulcer without direct X ray evidence, or to diagnose cancer of the stomach without evidence of occult blood in the stools. The fractional test-meal had also led to far more precise diagnosis. Dealing with the treatment of gastric ulcer, he said that the first factor to be dealt with was the acid factor, and this must be combated by diet and by such drugs as belladonna and alkalis. The second factor was that of focal sepsis; he doubted whether any ulcer could occur without such a factor. He stressed the importance of sinus infection and residual infection in the jaws of edentulous patients, to be found only by careful radiography. The other factors of importance were tobacco, worry, and fatigue. The latter factors necessitated treatment in bed. He showed by charts the effect of small feeds at frequent intervals in preventing the appearance of free HCl even when no alkali was given. Repeated X ray examination and search of the stools for occult blood were of value in demonstrating the progress of treatment. As regards after-treatment, he stressed the importance of an ulcer diathesis. Recurrences were usually due to a return to faulty habits, which must be prevented. Recent work had shown that bismuth salts were ineffective as alkalis whereas sodium citrate had high anti-acid powers; it was valuable in that its use involved no risk of alkalosis. Tribasic magnesium or calcium phosphate was also of great value and preferable to sodium bicarbonate and magnesium hydroxide. In conclusion Dr. Hurst spoke of the value of gastric lavage in pyloric obstruction; cicatricial obstruction was rare and would not result if the cases with spasmodic obstruction were rapidly treated. In chronic gastritis, associated with achlorhydria and excess of mucus, great improvement followed gastric lavage with hydrogen peroxide solutions.

Dr. T. Izod Bennett (London) said that it was perhaps difficult to speak of recent advances in the treatment of peptic ulcer at a time when the treatment adopted by many of the physicians chiefly interested in this subject had not yet been accepted by the professional in general, although such treatment had been successfully in vogue for ten years or more and had not been greatly modified during that period. He found that surgeons were inclined to condemn physicians merely because they were not magicians; the physician did not expect to cure except by the logical application of certain scientific principles over a period of time which must in some cases be somewhat lengthy. The essentials for successful treatment were, said Dr. Bennett, as follows:—

1. The removal of all sources of focal sepsis.
2. Prolonged and efficient arrest and neutralisation of gastric hyperacidity.
3. The reduction of peristaltic movements in the stomach and duodenum by an appropriate diet given at suitable intervals and so prescribed that the diet itself would exert a neutralising or adsorbing effect on acid.
4. The maintenance of active treatment during a period sufficient to secure permanent healing.
5. Prophylactic treatment aiming at the prevention of relapses.

All of these essentials were important and many of them were missing or insufficiently emphasised in treatments devised prior to that of the late Dr. Bertram Sippy. From a different point of view few of the treatments recommended were exactly on the lines of Sippy's because diets had to be devised to meet the requirements of patients of different nationalities. Prof. W. C. Alvarez, of Rochester, recently stated he had never seen a patient seeking relief for peptic ulcer who had, in his opinion, been efficiently treated prior to his first consultation with him, and it was a fact to-day, said Dr. Bennett, that the vast majority of patients coming under observation had never had treatment in which it could be claimed that the essentials outlined above had been carried out. Alkali is frequently given and alm invariably in insufficient dosage. Patients are trea for weeks and often undergo severe operations with important sources of oral sepsis ever being remov It is an easy matter to relieve the pain for a pati with gastric or duodenal ulcer, in most cases restricted diet and the administration of alkali, unless such treatment is carefully planned and car out for months after all symptoms have finis relapse is almost sure to follow. In his opin patients should be seen in consultation at reg intervals of three months or six months for a l time after they are apparently restored to full hea and at such consultations care should be taken to that oral sepsis has been removed, that food likely promote excessive peristalsis or hypersecretion being avoided, and that large meals are never tak reliance being placed on intermediate feeds to sec adequate nutrition. Proper attention to these po led to successful results.

Dr. J. H. Anderson (Ruthin) stressed the imp ance of coöperation with the patient. Three mo was the minimum time for strict treatment; the month should be in an institution; the second mo as convalescence, and during the third a gradual ret to work could be begun. After-treatment should on for at least two years under supervision consultation with his own doctor. The appe was an additional source of infection and should removed if necessary, but after-treatment sh again be in the hands of a physician. Regarding he advocated a graduated diet beginning with o oil and egg and milk at two-hourly intervals, bo rice and pounded chicken being gradually ad By the twentieth day dry toast, steamed fish, custa and milk puddings are given. At the end of the mo a light bland diet with olive oil between meal given. The rate at which the diet can be incre varies in individual cases and must be determ according to progress. Of alkalis he supported use of magnesia salts, although the subject of most suitable alkali was still being examined. agreed with Dr. Izod Bennett as to the necessit time to secure firm healing.

Dr. P. Hamill (London) stressed the necessit impressing on the patient the fact that his cure in his own hands. He felt that elaborate syst were bad because of the difficulty of applying t at home. He agreed with Dr. Hurst as to the valu sodium citrate. Ten grains of magnesium oxide w neutralise 10 oz. of gastric juice as secreted, 10 magnesium carbonate or chalk, on the other h would only neutralise 4 oz., and bismuth was al without effect. Citrates were valuable for avoi the clotting of milk. The value of atropin preventing spasm was to be remembered. It remarkable how readily patients with gastric tolerated olive oil. A most important adjuvan treatment was the use of blood transfusion in which had had severe hæmorrhage. Duodenal fee was sometimes of great value in cases where obsti pain and vomiting prevented adequate nutr under oral administration.

Dr. A. P. Cawadias (London) emphasised the that focal infection was but one of many fac amongst which constitutional factors in the endo system were equally important. He thought pr shock therapy was very valuable in alleviating and hastening healing.

The President, Dr. W. Langdon Brown (Lon summing up the discussion, said that he felt stomach was often more sinned against than sin being an organ essentially resistant to disease. felt, however, that gastric ulcer was a disease v had become commoner without obvious cause. R feeding had rightly fallen into disrepute. He that the Lenhartz diet had been a great advan its day, but modern treatment recognised importance of the individual patient's requirem The importance of hydrochloric acid as a germ was being more fully recognised, and the admin tion of this acid in cases of achlorhydria was of

ortance. He praised the work of Gibson and ers in putting on a firmer basis our knowledge of alkalis of real value. The pendulum was swinging nst the tendency to operate hastily. Hæmorrhage no longer an indication for operation before quate medical treatment had been tried. He luded by refuting the doctrine enunciated at the cer Conference that all ulcers should be excised account of the risk of malignant change. The ence was that gastric cancer almost invariably e in cases where there was no sign of any previous ase of the stomach, and the public were already ciently alarmed about cancer without the intro- ion of such a bogy.

r. HURST, in reply, emphasised the importance of nic gastritis as revealed by fractional gastric ysis. He briefly reviewed the results of surgical tment of gastric ulcer; the mortality of gastrec- y in a famous hospital was 15 per cent.; the tality of medical treatment was nil and there were tically no cases which could not be cured medically oper care was given to them.

FECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 11TH, 1928.

otifications.—The following cases of infectious ase were notified during the week:—Small-pox, (last week 111); scarlet fever, 1322; diphtheria, ; enteric fever, 174; pneumonia, 592; puerperal r, 45; puerperal pyrexia, 99; cerebro-spinal fever, 5; e poliomyelitis, 14; acute polio-encephalitis, 1; phalitis lethargica, 20; continued fever, 1; dysen- , 22; ophthalmia neonatorum, 132. No case of era, plague, or typhus fever was notified during week.

e following counties each notified three or more cases teric fever:—London, 40; Devon, 6; Essex, 28 (of these om Colchester); Kent, 9; Lancaster, 13; Middlesex, 7; olk, 4; Southampton, 7; Surrey, 11; Warwick, 3; Yorks, Riding, 5; City of York, 5. The total of 174 includes ases of paratyphoid fever, of which 37 were notified in on and 6 in Surrey.

e number of patients in the Infectious Hospitals of the opolitan Asylums Board on August 21st–22nd was as vs:—Small-pox under treatment, 12; scarlet fever, ; diphtheria, 1553; enteric fever, 120; measles, 169; ping-cough, 216; puerperal fever, 15 (plus 7 babies); phalitis lethargica, 71; poliomyelitis, 2; "other ses," 16. At St. Margaret's Hospital there were 19 s (plus 11 mothers) with ophthalmia neonatorum.

eaths.—In the aggregate of great towns, including don, there was no death from small-pox, 7 (5) from ric fever, 12 (1) from measles, 2 (0) from scarlet , 23 (4) from whooping-cough, 23 (6) from theria, 72 (18) from diarrhœa and enteritis under years, and 27 (5) from influenza. The figures in ntheses are those for London itself. The monthly ment of deaths from small-pox contains the mation that no such death was returned for the th of July.

e fatal cases of enteric fever outside London were ted from Leyton and Rochdale. Of the 19 fatal cases hooping-cough outside London 6 were reported from ingham while Glasgow reported the same number that . Of deaths from diarrhœa Liverpool reported 11; her town in England and Wales outside London more 4, but Glasgow 7 and Dublin 8.

number of stillbirths registered during the week 299 in the great towns (corresponding to a rate per 1000 births), including 48 in London.

REVOLVING OPEN-AIR HOUSE.—The West London ital at Hammersmith has been presented with a ving open-air house which has been placed on the flat of one of the wings. It has been the practice to place lescent children on the roof in settled weather, but evolving house now enables them to take shelter in vent of rain. The house will hold from seven to ten ren.

VITAL STATISTICS OF ENGLAND AND WALES.

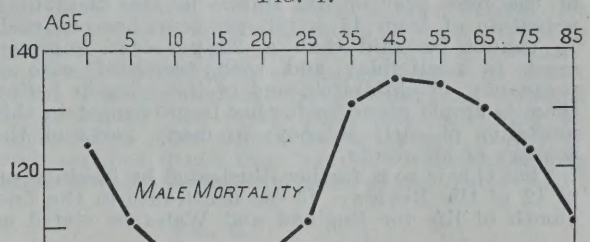
THE REGISTRAR-GENERAL'S REVIEW OF 1926.

THIS third of the volumes[1] in which the General Register Office now presents its annual statistical review is one which is, or at least ought to be, eagerly looked for by all medical officers of health and others interested in the incidence of disease. In fact, we fear it is read by few, and there can be no question that the public health service is the poorer by this default. The health officer who has studied this annual volume has increased his competence for his routine work year by year; he has had suggested to him problems for research which he can pursue; and his faith is fortified in the belief that for the pursuit of such researches there is not needed that knowledge of higher mathematical methods, fear concerning which has restrained timorous persons from inquiries of real public value. The present volume is perhaps the most interesting of a series of valuable medical reports which appear year by year; we can only hope to touch on a few points illustrative of the further riches waiting for extraction from a rich storehouse.

Progressive Ageing.

The progressive ageing of the English population is a phenomenon which it is difficult always to remember, although it has momentous bearing on our present and prospective vital history. The fact that the female

FIG. 1.



death-rate in England and Wales last year was only 10 per 1000 illustrates the importance of remembering that the steadily falling birth-rate is now meaning a relatively small proportion of children under 5, and will before long mean a larger proportion of persons over 55, whose death-rate is higher than that at intermediate ages. It is very easy to fall into the error that such a death-rate means an average duration of life for each person of 100 years. In truth, it only means a duration of about 59·6 years, owing to the facts just mentioned. Hence the necessity for the standardised death-rates used throughout this report, in which adjustments are made for these excesses of persons at certain ages, as compared with an arbitrary standard population.

Much interest attaches to the death-rates in the two sexes at different ages. In Fig. 1 these are shown graphically in relation to each other. Let the straight be the death-rate at such successive age-period for females. Then the upper curve gives the corresponding male death-rate. The curve of the male death-rate is profoundly interesting. At ages 0–5 the male is 24 per cent. in excess of the female death-rate, an

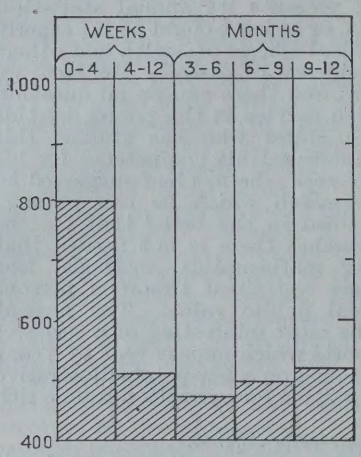
[1] The Registrar-General's Review of England and Wales, 1926, Text. 5*s*.

early female superiority of which no full explanation has been made. Between 10 and 25 the male inferiority is only some 4 or 5 per cent.; but at ages 45–55 the male death-rate is some 35 per cent. in excess of that of women. As old age approaches so do the death-rates for the two sexes come nearer together.

Infant Mortality.

The whole question of infant mortality is dealt with exhaustively, and the student will find here data bearing on every phase of this multiform problem. We can only draw attention to one point. This relates to the constantly reiterated statement that practically no progress has been made in securing a reduced death-rate during the first four weeks after live birth. The real facts are shown in Fig. 2. Comparing the average experience of 1906–10 with that of 1926, it will be seen that at this earlier period of "irreducible" mortality a reduction of over 20 per cent. has been experienced; while at the four subsequent divisions of the first year of life shown in the diagram a reduction of from 47 to 52 per cent. has occurred. It cannot be said that a 20 per cent. improvement is negligible; and with increased care of pregnancy, of childbirth, and of the lying-in period there is ample room for further improvement in this mortality of early infancy—in many parts of the country at all events.

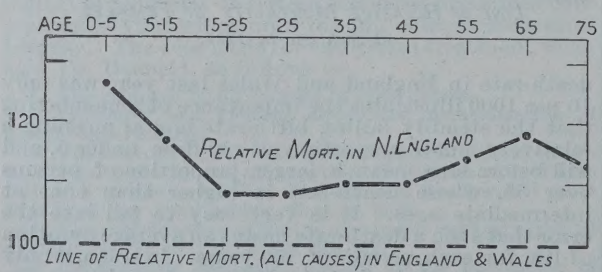
FIG. 2.



Relative infant mortality in 1926 as compared with that in 1906–10 taken as 1000 for five consecutive age-periods in infancy.

That this is so is further illustrated by Table X. on p. 12 of the Review. If the death-rate in the first month of life for England and Wales be stated as

FIG. 3.



100, it is highly significant that it is as high as 116 in the north of England and only 82 in the south! It is incredible that this difference between north and south is intrinsic and is not a difference in the degree of liberation from the barbarism of lack of skill or care.

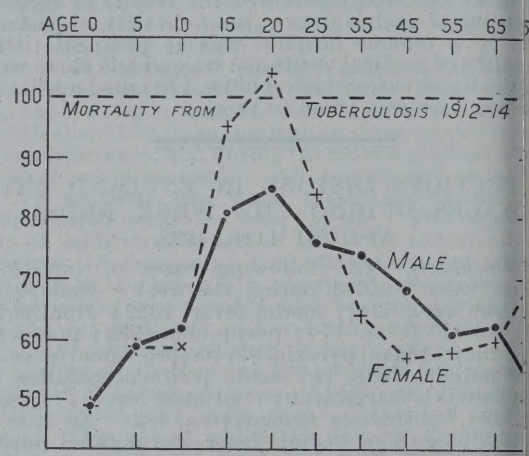
Total Death-rates North and South.

That this latter explanation holds is confirmed by the experience of north and south as regards total death-rate from all causes at successive periods of life. Fig. 3 shows the percentage excess of the northern areas of England over the average for England as a whole in the year 1926. This excess, which as shown in previous reviews, is not limited to industrial towns, calls for painstaking health inquiries in each northern community. The diagram contrasts north with the whole of England. Evident north were contrasted with south the contrast w be even greater.

Tuberculosis.

The whole of this section of the Review shou studied by tuberculosis officers and others. amount of improvement in the registered death from total tuberculosis, when so recent a perio 1912–14 is compared with 1926, is shown in Fi Even after allowance has been made for the fact the decrease of tuberculosis at ages 0–5 ma exaggerated owing to changes in nomenclature reduction shown at ages is most striking will be noted that actual death-rates for each

FIG. 4.



Relative death-rate from total tuberculosis in 1926 for eac and all age-periods compared with the corresponding ra 1912–14 taken as 100.

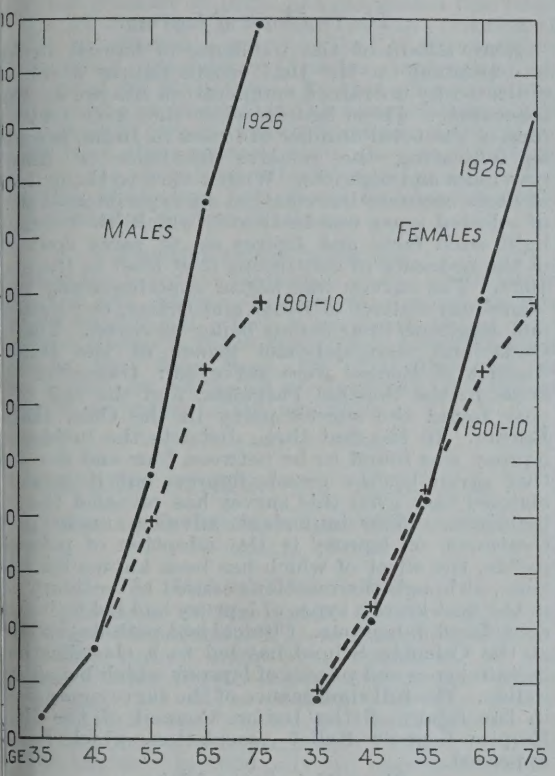
period are not shown in this diagram, but percentage difference of the death-rate (mal female) in each age-period from that of 1912–14. males it is seen that reduction has been experie at all ages, and that even at the age-period 15–20 decrease is 19 per cent., while at the age-period 2 it is 15 per cent. The smaller decrease at these than at other ages indicates a continuance of inir influences which remain to be studied and remo The course of the female relative death-rate bi out this point even more strikingly. At ages 15–2 reduction in the tuberculosis death-rate is only cent. and at ages 20–25 it has actually increase 4 per cent. It is impossible to avoid connecting increase of the female death-rate in early adult with the increasing migration into towns and assumption of industrial and commercial in lie domestic life.

Cancer.

The section of the Review dealing with malig disease is so important as almost to call for a sp article. Doubtless this section of the report wi more eagerly scanned than any other, and it ma hoped that it will serve to temper and curtail rash statements on the statistics of cancer which i with monotonous inaccuracy. In view of exaggerated statements as to increase of ca Fig. 5 is very instructive. It is drawn Table XLIII. on p. 64 of the Review. The distributed cancer death-rate at successive dec of life from 35 onwards for 1901–10 is compared that of 1926, for males and females separa Earlier ages are ignored, as the cancer death-ra almost negligible prior to age 35. In both males females an increased death-rate is shown, but th practically limited to ages over 55 and does become serious until the age of 65 is reached. shows in the first instance the folly of writing a crude death-rates from cancer and the need so-called standardisation. When this is done

istered increase at all ages in male cancer between 1–10 and 1926 is 30 per cent.; according to the de death-rate it is 71 per cent. One must remain

FIG. 5.



h-rates per million at each age-period 35–45 to 75 and upwards n cancer in the two sexes, 1901–10, being compared with 1926.

ome doubt as to the extent to which the increase ancer at the higher ages is real, and the extent to ch it is due to increased accuracy in diagnosis and cially to the greater frequency with which skilled opsies are now made. In this nexion it may be noted that stered cancer mortality is highest he denser centres of population, as pointed out in the Review, excess in urban centres is much ter for males than for females. s well-known that the proportion inaccessible growths, liable to pe recognition as cancer, is much er for the male sex.

noteworthy fact is that since 3 there has been a practical nce of recorded increase of cancer females, there being no increase ortality from accessible growths a comparatively slight rise for ers in females of inaccessible s. An important statement on 68 of the Registrar-General's iew is based on a revision of rmer comparison made between er in accessible (easily diagnos-) and inaccessible parts of the y. In a preceding review such a parison showed definite increase ccessible cancers, a result sup-ing the view of continuing ease in the death-rate from er. More recent returns, however, show that r both sexes alike, there is no longer any ence afforded by the comparison of accessible inaccessible sites in favour of the reality he recorded increase."

The interpretation of this result, which fits with observations made many years ago on the statistics of Frankfort-on-Main by King and Newsholme, is of course doubtful. It may mean that any apparent increase in inaccessible cancer is due to improved diagnosis; or, as pointed out in the Review, the facts are capable of an explanation of a totally different character. It may be that surgery has secured for the community a stationary position in the death-rate from "accessible" cancers which otherwise would have displayed a death-rate increasing like that of "inaccessible" cancers. Who shall decide? This opens up the great question as to the extent to which death certificates can be trusted to state

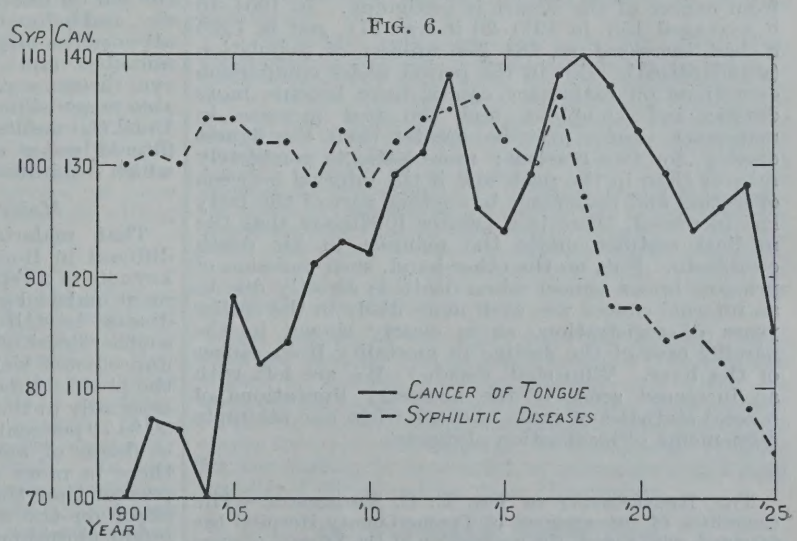
Death-rates from Cancer per Million Living.

Site of disease.	Males.	Females.
Lip, tongue, jaw	105	15
Pharynx and œsophagus	79	18
Stomach and liver	283	223
Intestinal (not rectum)	132	135
Rectum and anus	107	60
Uterus, ovary, vulva	—	206
Breast	2	184
All sites	1010	994

the localisation of the primary growth when death occurs from cancer. For instance, if several years after a successful operation for cancer of the tongue or mamma (i.e., successful in the sense of no recurrence in the same site) a patient dies of cancer of the liver or some other internal organ, in what proportion of such cases is the primary site of cancer stated in the death certificate? It is hoped that this is usually done, as it ought to be always; but is this view consistent with probabilities; and if not, what is the unknown margin of error? On the individual answer to this question must depend the weight attaching to consideration of death statistics for cancer of various sites. We regard as extremely important the statistics of localised cancer published in the Registrar-General's Review, and trust they will be continued, for every year they will tend to approximate more closely to the natural history of each certified death from cancer. Notwithstanding the inevitable doubt expressed above, Table XLV. on p. 69 of the Review is intensely interesting. In the table of death-rates from cancer we give an incomplete summary of its larger items.

The table, and still more the fuller table from which it has been extracted, is pregnant with suggestions

FIG. 6.



Relative (not actual) death-rates from cancer of the tongue and syphilitic diseases, the death-rate for each of these in the year 1900 being taken as 100.

for further research, and invites immediate speculation—which may lead to research—as to the causation of the extraordinary sex differences in the incidence of fatal cancer. Why this excess of cancer of the mouth in men? Is it due to their lower standard of oral hygiene? Is it due to smoking or to the drinking of strong alcoholic spirits, or to syphilis? To this point we return later. Does a similar explanation apply to the excessive male cancer mortality of the pharynx and stomach. Or do other indulgences of the table explain the difference? The possible relation of uterine cancer to avoidable traumatism in child-bearing necessarily arises, and the fact that mammary cancer is increasing unlike uterine cancer calls for separate investigation.

Preceding remarks have a bearing on a diagram on p. 72 of the Review displaying a most suggestive comparison between the course in recent years of mortality from cancer of the tongue and from syphilis. In Fig. 6 the course of the death-rate from cancer of the tongue and that for the death-rate from the diseases which collectively give a fair index of fatal syphilis in the community are compared. In each case we have reduced the death-rates to a relative amount, each death-rate being given in proportion to the initial item stated as 100. The earlier part of the cancer curve shows a rapid increase in the death-rate from cancer of the tongue without any evidence of relation to the syphilitic death-rate. This may or may not indicate increasing accuracy in certification of the original site of cancer, or it may or may not mean an actual increase of cancer of this site, or both. The second half of the two curves from 1914 onwards displays a suggestive parallelism, though the Review is most cautious in deprecating premature pronouncement on this point. The general course of the curves shows that with decreased syphilis has gone decreased cancer of the tongue (as certified in death-returns) and confirms the wide pathological impression that there is a causal relation between the injury produced by earlier syphilitic lesions and later cancerous changes. As pointed out in the Review, "decrease of syphilis is not the only influence making for decrease of lingual cancer known to have been operative during the last few years." Among other influences may be mentioned improved dental care.

The continuing increase in the death-rate recorded from cancer of the breast is intriguing. In 1901–10 it averaged 158, in 1911–20 it was 171, and in 1926 it had increased to 184 per million of population (standardised). But in the period under comparison operations on mammary cancer have become more drastic and complete, and the real increase in mammary cancer may be greater than the figures display, for two reasons: more patients completely recover than in the past, and if the interval between operation and recurrence in another part of the body has increased, there is a greater likelihood that the medical certifier omits the mamma in his death certificate. But, on the other hand, such omission of primary breast cancer when death is directly due to an internal cancer was even more likely in the earlier years of registration, as is clearly shown in the parallel case of the decline in mortality from cancer of the liver. Who shall decide? We are left with an increased sense of the necessary limitations of massed statistics of cause of death when one attempts refinements of localisation of disease.

THE RETIREMENT OF DR. E. C. THOMPSON.—The committee of management of Tyrone County Hospital has accepted, with regret, the resignation of Dr. Edward Charles Thompson, who was appointed surgeon to the hospital in March, 1875. He succeeded his father, who had held the appointment for 40 years, making a total, for father and son, of 93 years' service. Dr. Thompson, who early in life received the Albert Medal and the St. John's Medal for bravery in saving life on land, sat in Parliament as a Constitutional Nationalist for North Monaghan from 1900 to 1906. He was formerly President of the North of Ireland Branch of the British Medical Association.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

The Incidence of Leprosy.

KNOWLEDGE of the incidence of leprosy in I is dependent on the 1921 census figures which collected by untrained enumerators and are avow inaccurate. These figures, while they give very idea of the total number of lepers in India, are u as indicating the relative incidence in diff provinces and districts. With a view to the colle of more accurate information an experimental su of selected areas was instituted which has brough light such facts and figures as to carry convi of the necessity of continuing it at least to the e 1928. The survey was begun experimentally in Manbhum district of Bihar and Orissa, the Manb and Raghunathpur *thanas* being surveyed. Ther Onda and Gangajalghati *thanas* of the Ban district of Bengal were surveyed; thereafter t areas in the Sonthal Parganas, and the end of year found the survey party in the Chin Hill Burma. In the first three districts the inciden leprosy was found to be between four and five t that given by the census figures, but it canno claimed that even this survey has revealed the t incidence. The important advance made in treatment of leprosy is the adoption of potas iodide, the effect of which has been known for a time, although the reactions caused by ordinary c in the best known types of leprosy had led to its b considered dangerous. Clinical and pathological s at the Calcutta School has led to a classificatio certain types and phases of leprosy which benefit iodide. The full significance of the survey may be in the report of the Indian Council of the Br Empire Leprosy Relief Association, which has appeared.

Street Watering and Disease.

A prominent public health authority has a drawn attention to the dangers associated with indiscriminate use of unfiltered water for sprayin streets of Calcutta. The water that is used for spra is drawn from the most polluted portion of the ri it is practically raw sewage. When the silt th thrown on the streets along with the water is n dry, and before it is sterilised by the sun, it is scatt all over the city by the wind. The dust teems microbes and is undoubtedly a potent caus eye, throat, ear, and nose ailments in the city. also responsible for many cases of septic pneum Until the unfiltered water-supply is stopped and filtered water used Calcutta will remain a cit which respiratory complaints flourish.

Malaria Problem in Bombay City.

That malaria has become much more w diffused in Bombay within the last 15 years is keynote of a report presented recently by the Go ment malariologist to the Bombay Corporation. disease is still prevalent to a serious extent in southern part of the city, due chiefly to the presen unprotected wells; but the most intense malar the present time is in the vicinity of the mills, especially in the Worli section. In certain areas 30 to 70 per cent. of the children examined have sh evidence of malarial infection. It is possible there is more endemic malaria in Bombay at present time than there was in 1911. Apart fro effect on the health of the population and on infant mortality of the city, the disease is the cau very heavy financial loss to the city. There i natural malaria in Bombay, the chief reason bein absence of natural streams. The cause of its p lence in the city is the presence of thousand permanent breeding-places artificially produce man, the most important of which are wells, cist fountains, tanks, water used in building construc leakages from reservoirs, water-pipes, and cellars

hich subsoil water percolates. Preventive measures ıve hitherto failed owing to lack of a unified control antimalarial operations.

Pasteur Institute at Kasauli.

The Government of India has recognised the value the work done by the Pasteur Institute of India at asauli in offering a grant of Rs.1,14,500 towards on-recurring expenditure besides increasing the nual grant by Rs.10,000. To this offer, however, as attached a provision that this financial help would e given only in case the Institute raised an equivalent nount from other sources, which may be a difficult sk. In the meantime rebuilding is urgent. The aharajah of Dholpur has offered Rs.12,000 towards e provision of electric lighting.

Daylight Saving in Burma.

Among the items for discussion at the forthcoming ssion of the Burma Legislative Council is the aylight Saving Bill, which is unique in India. The oposal is similar to the Summer Time Act in England namely, that from Sept. 1st until April 1st all ocks should be advanced an hour and all business rried on according to the new time.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Medical Civil Service.

THE standards of the public health service in nerican municipalities still leave much to be desired. a recent survey made by a committee of the nerican Public Health Association it was found at among 1281 State, county, and city health icers, listed by the U.S. Public Health Service up the beginning of this year, only 29 had a degree public health. In 1926 only 104 degrees in public alth were granted in our Universities, whereas has been estimated that the needs of the country a whole require that 570 health officers should be ined each year. It is obvious that men are not racted by the profession. Probably the outnding reason for this is the insecurity of tenure public health office. It will be remembered how e president of the association recently lost his ice in Chicago on purely political grounds. In 6 cities investigated it was found that in less than per cent. was the office regulated by civil service. out one-quarter of these cities appoint their alth officers for a term of not more than two years, s than half of them make the appointment "indefie, or at the pleasure of the appointing body." As result of these conditions applicants must either excessively devoted to public service or very lly in need of employment before they are willing accept office.

Criticism of the B.C.G. Vaccine.

S. A. Petroff and Arnold Branch, of the Trudeau natorium, as a result of a very thorough search of literature and of their own laboratory experiments h B.C.G. vaccine, come to the conclusion that vatchful waiting is the best position at present in erence to the vaccination of infants." Contrary the findings of many European workers, these nerican workers do not find the vaccine constantly ocuous to small laboratory animals. In two itances they were able to demonstrate generalised erculosis by direct inoculation into guinea-pigs al in one other instance tuberculosis was established er the second animal passage. Noticing that when .G. was grown on fluid media there appeared two es of colonies, the Trudeau workers became picious of the existence of variants similar to those erved in the reproduction of other acid-fast anisms. A small amount of culture received ectly from Calmette was triturated in salt solution, ered through two layers of Whatman paper No. 5, and plated on a gentian-violet medium. After six weeks there appeared two morphologically distinct types of colonies. A comprehensive study of the biology of these two types is to be published shortly. Suffice it to report here that while the type christened "R" always produces some tubercles which in time heal, the type they have named "S" invariably produces progressive disease terminating in the death of the guinea-pig. As regards the reports of successful infant inoculation in Europe they criticise especially the lack of adequate control. They would like to see a series of thoroughly controlled experiments in cattle and on a large scale.

International Congress of Mental Hygiene.

The first International Congress of Mental Hygiene, it is announced, will be held in Washington in the spring of 1930. The meeting was to have been held in 1929, but has been postponed in order to secure greater coöperation with psychiatric associations in this country. It is believed at present that a large and representative attendance of American psychiatrists is now assured. Information on the progress of the plans for the conference may be had by writing to the general secretary, Mr. Clifford W. Beers, 370, Seventh Avenue, New York City.

Small-pox in 1927.

For the fifth year in succession the United States reported more small-pox cases than any other country except India, a total of 38,498 cases for 1927 as against 33,343 cases in 1926. There were, however, only 135 deaths. The New York State Department of Health has been commendably thorough in obtaining vaccination histories for every one of the 368 cases reported in their jurisdiction. Analysis shows that not a single case occurred among those vaccinated successfully during the last seven years; 31 cases occurred among those vaccinated more than seven years previously, and the remaining 337 among individuals who have never been successfully vaccinated.

The Ethics of Pay Clinics.

The Medical Society of the County of New York recently appointed a special committee to inquire into the relation between the pay clinic (for people able to contribute towards the cost of the service rendered) of Cornell University and the practising members of the profession. The committee reports in part as follows:—

1. The welfare of the public must be the first consideration of a medical problem, the economic difficulties of the physician being of secondary importance. 2. The Cornell Pay Clinic was a decided departure from the prevailing type of dispensary: (*a*) in that an attempt was made to charge fees that would make the clinic self-supporting; (*b*) in that a diagnostic group clinic was formed for persons of moderate means. 3. There is at present in New York no other dispensary which excludes the indigent poor and to which the person of moderate means may go and have a thorough diagnostic study within his capacity to pay. Less than 20 per cent. of the work of the Cornell Pay Clinic is diagnostic. Over 80 per cent. is devoted to the routine treatment of patients. The clinic is thus in active competition with physicians who earn their living.

The committee concludes that the Cornell Clinic does not actually violate any State law; it does not object to Cornell holding a diagnostic clinic for teaching purposes, provided such a clinic is subsidised by the University, but it is opposed on principle to pay clinics for treatment under all circumstances. Counsel for the Society is instructed to investigate the legal aspects of the situation more thoroughly.

Rocky Mountain Spotted Fever.

Recent investigations into the ætiology and prevention of this disease were reported by Dr. R. R. Parker, of the U.S. Public Health Service, to the Fourth International Congress of Entomology now being held at Ithica, New York. There is a remarkable variation in the case-mortality of this tick-borne disease. In some parts of Montana the fatalities amount to 90 per cent. of the case-incidence,

whereas in the neighbouring State of Idaho the case-mortality has been no higher than 5 per cent. During the last few months, however, the use of a serum has been definitely effective in cutting down the death-rate.

THE GERMAN SICKNESS INSURANCE SYSTEM.*

THIS volume, the latest addition to the valuable series of publications issued by the International Labour Office on the subject of national health insurance, fully maintains the high standard set by its predecessors. It is evidently the fruit of much study and reflection and should be found useful by those who in other countries are grappling with the various problems of sickness insurance. Hitherto the recent experience of compulsory insurance against sickness in the land of its origin has been almost inaccessible to English readers who do not read German, for the two leading books in English on the subject, Mr. Dawson's "Social Insurance in Germany" and Mr. Gibbon's "Medical Benefit in Germany and Denmark," were published in 1912, and much has happened to the German insurance system within the past 16 years. To English readers, therefore, this book makes an especially welcome appearance.

Compulsory insurance against sickness on a national scale in Germany dates from June, 1883, although the principle of compulsion had already been introduced in various parts of the Empire; in Prussia miners had been compulsorily insured since 1854. At first the national scheme applied only to persons employed in certain named occupations, but others were added from time to time, especially by the important Act of 1911, which brought agricultural labourers and domestic servants within the scheme. At the present time the number of insured persons is rather more than 20,000,000, or nearly one-third of the total population. In Germany, insurance is compulsory not only against sickness, but also against invalidity and old age, and against industrial accidents (workmen's compensation). Each of these three forms of insurance is administered by a separate body of organisations; sickness insurance by the sickness funds (*Krankenkassen*), which are self-governing associations of insured persons and contributing employers; invalidity and old age insurance by the local insurance authorities, which are bureaucratic institutions with some representation of insured persons and employers; and accident insurance, to which the employees do not contribute, by mutual associations of employers. Moreover, sickness insurance is not regulated by a single code as in this country; there is a separate body of law for wage-earners, and another for salaried employees, while miners are insured under special Acts which provide a single system of sickness, invalidity, and old age insurance. The whole subject is exceedingly complex and difficult to understand, and Dr. Goldmann and Dr. Grotjahn are to be congratulated on the very considerable measure of success they have achieved in explaining it to the general reader.

Tendencies of Sickness Insurance.

Compulsory sickness insurance appears everywhere to develop on certain broad lines, which may most profitably be studied in Germany, where insurance on a compulsory basis has existed longer than in other countries. First, the proportion of the total population coming under insurance tends continually to increase, partly by the inclusion of additional occupations, but chiefly by the extension of insura benefits to the dependents of the insured pers This extension has made great progress in Germ since the war, and it is now estimated that in addi to the 20 million insured persons there are ne 19 million dependents for whom benefits are avail under the sickness insurance system, the total nun forming more than three-fifths of the whole pop tion. Secondly, cash benefits have become relati less important than benefits in kind—medical tr ment, &c. Experience has shown that it is n economical to provide the treatment necessary restore working capacity than to provide the disa worker with money to use at his own discret Consequently, the range of treatment provided by sickness funds has greatly increased. Thirdly rapidly increasing activity is being displayed in field of prevention.

Range of Treatment.

Treatment is given on a scale that is surpri to the English reader. The insured person Germany is not only entitled to the services general practitioner, as in this country, but he also provided for him the whole range of mo therapeutic measures—specialist services, inclu electro-physical, balneological, and orthopædic tr ment, and treatment and maintenance in sanatori and other residential institutions. Treatment ma given by arrangement between the sickness f and outside institutions, but in many cases the fu make direct provision in their own institutions. General Local Sickness Fund of Hamburg has institutes for artificial sunlight therapy and a l orthopædic institute for making appliances, w in 1925 there were made 5424 trusses, 16,305 flat-supports, 3352 abdominal belts, and nearly 18,000 o articles. In 1924 no less than 19,906 X ray exam tions were made in the institute of the Associa of Berlin Sickness Funds, and 13,715 in the Insti of the Dresden Local Sickness Fund. Diagn facilities are provided on a large scale. The Insti of the Association of the Berlin Sickness Fu contains chemical, pathological, bacteriological, serological departments, and makes between 5000 6000 examinations monthly. In 1924 it was sulted by about 3000 insurance doctors in Be In-patient hospital treatment is usually provide arrangement with institutions established by communes or voluntary organisations, but s funds have established hospitals of their own; miners' funds have 21 hospitals with 3970 beds.

Dental treatment is given on a rapidly increa scale. There are some 8000 dentists in Germ and about 6000 are employed by the sickness fu The average expenditure on dental treatment member by the funds rose from M.0·50 in 191 M.2·35 in 1925. In the Hamburg funds the ave expenditure in the latter year was M.3·72 per mem

Preventive Work of the Sickness Funds.

In recent years there has been a remark development of the preventive side of sick insurance. For instance, special attention is give maternity and child welfare. The statutory mate benefits, which are provided for both insured their dependents, include (1) attendance by a mid and, if necessary, medical attendance; (2) a lump payment of M.10; (3) a weekly payment during four weeks preceding and the six weeks follo confinement; and (4) an additional weekly payment during 12 weeks after confinement to t mothers who nurse their babies. The funds tribute to the communal maternity and child we centres, and some have established centres of t own, which are widely consulted; the centre of Erfurt Sickness Fund is consulted by nearly 80 cent. of the mothers of the area. Dr. Goldmann Dr. Grotjahn think that the effort put forth in direction is still inadequate, but there seems no d that an enormous amount of good work is b

* Benefits of the German Sickness Insurance System. By Franz Goldmann, M.D., and Alfred Grotjahn, M.D. International Labour Office. Studies and Reports, Series M (Social Insurance), No. 8. Published in the United Kingdom for the International Labour Office by P. S. King and Son. 1928. Pp. 188. 4s.

e. The funds participate in welfare work among ool-children, they contribute towards the provision country homes, forest schools, open-air baths, ies, &c. Some funds maintain their own country itutions; the Sonneberg Fund has its own forest ool, where the children have facilities for sun hs, swimming, gymnastics, &c. Contributions are le towards school meals; in 1925 the Cologne ds contributed 45 per cent. of the cost of the ls provided by the municipality for school-dren. Many funds provide orthopædic gymnastics the children of the members.

n the antituberculosis campaign the lead, so far he insurance organisations are concerned, has been en by the invalidity insurance institutions, but sickness funds are now taking an active part in work. The facilities they afford for free medical mination, with various kinds of specialist assist-e, tend to the early detection of the disease, and sick visitors of the funds encourage the members seek medical advice when disease is suspected. funds contribute largely to the maintenance of atoriums and dispensaries and some have estab-ed institutions of their own. What is regarded an important health measure, especially in this nexion, is the provision of convalescent treatment recuperation in country convalescent and holiday nes, forest camps, &c., particularly for young kers newly exposed to the stress of economic oloyment. The funds participate in the anti-hol and antivenereal movements, and a system compulsory notification of venereal disease, with ervision of the patients, has been instituted by a nber of the funds. Much health propaganda is ried out by such means as the distribution of phlets and periodicals, the organisation of lec-es, health exhibitions, films, plays, &c. The tral Union of German Sickness Funds publishes nonthly health journal which has a circulation of rly half a million. The first German "Health ek" was organised jointly in 1925 by the muni-ality of Berlin and the sickness funds, and this was owed in 1926 by a "National Health Week" ely owing to the efforts of the funds.

The Sickness Funds and the Medical Profession.

he extensive range of the medical services vided by the sickness funds brings them into e relation with the great body of the medical fession in Germany. It is estimated that about 00 doctors, or 80 per cent. of the whole profession, k for the funds, and that for the great majority work forms the chief source of their income. Goldmann and Dr. Grotjahn estimate that more n half of all incomes from medical practices in many is derived from sickness insurance. The em of employment of doctors and the methods amount of remuneration differ widely amongst various funds, but the system of free choice of or, which is one of the basic demands of the ession, appears to be making headway. Before the funds were practically autonomous in ing arrangements with the doctors, but in that provisions were introduced into the Federal rance Code to regulate the doctors' contracts, so certain conditions of service are common to the le country. The funds, however, still possess a iderable measure of autonomy.

Some Criticisms of the German System.

he German sickness insurance system is a derful achievement in the field of social reform, as the authors of this volume do not hesitate to t out, it is by no means free from defects. The of the funds appears to be imperfectly dinated with the health work of other agencies there is much overlapping and duplication of t, which could be avoided by improvements in nisation. Again, the system has not succeeded in ning the vitally important object of securing onious relations between the administrative bodies and the medical profession, and our authors think that no real improvement may be expected until something like the British system is adopted under which the local arrangements with the doctors are made by an insurance committee on which the local medical profession is represented.

The utility of this volume to the foreign reader would have been enhanced if the authors had included a preliminary account of the general framework of the German social insurance system, explaining the organisation of the different agencies concerned in the various forms of insurance, their relation to each other and to the local authorities and the State. Certain technical terms—e.g., "basic wage"—might usefully have been defined and explained and the statistics brought to a later date than 1925, when for the most part they end. And the medical reader would have welcomed fuller information on the subject of the relation of the funds to the doctors, the nature of the problems that have arisen in that connexion, and the progress that is being made towards their solution. These, however, are but minor criticisms of an important work of sterling value and utility.

MEDICINE AND THE LAW.

Dangerous Drugs Legislation.

THE *London Gazette* of August 17th gave notice that the Dangerous Drugs Act of 1925 will come into force on Sept. 25th, 1928, that being the date when the International Opium Covention signed at Geneva in February, 1925, begins to operate. The notification will recall to our readers the abrupt termination of the proceedings against Colonel Kynaston, when counsel for the Crown admitted in the Court of Criminal Appeal that the Act of 1925 (cited, possibly unnecessarily, in the framing of the charges in that case) was not yet operative. The proceedings consequently resembled, as the Lord Chief Justice remarked, the pulling of a bell-rope when there was no bell at the other end. The Geneva Convention of 1925 provided (by Article 8) that, if the Health Committee of the League of Nations, after having submitted the question for advice and report to the Permanent Committee of the Office International d'Hygiène Publique in Paris, found that any preparation containing any of the narcotics referred to in Chapter III. of the Convention—i.e., drugs to which Part III. of our Dangerous Drugs Act, 1920, as amended, applies—could not give rise to the drug habit on account of the medicaments with which those narcotics are compounded and which in practice preclude the recovery of the said drugs, then the Health Committee should communicate the finding to the parties to the Convention and thereupon the provisions of the Convention should not apply to the preparation concerned. Our 1925 Act was passed to give effect to the Geneva Convention. The resultant changes in our dangerous drugs legislation are these: Part I. of our Dangerous Drugs Act of 1920 (regulating dealings in raw opium and restricting its import and export) is extended to coca leaves, Indian hemp, and resins obtained from Indian hemp, and all preparations of which such resins form the base. "Coca leaves" and "Indian hemp" are specially defined. Section 2 of the 1920 Act enacted that nobody should export raw opium from the United Kingdom except under licence and from approved ports, *and except in packages marked in the prescribed manner with an indication of the contents thereof.* The italicised words now cease to have effect. The 1925 Act also substitutes a new definition of the drugs to which Part III. of the 1920 Act applies, and a new definition of "medicinal opium." Finally, it authorises the making of Orders in Council excluding preparations from Part III. of the 1920 Act where there has been a finding under Article 8 of the Geneva Convention as already described.

Another notification in the same *Gazette* announces that Part III. of the Act of 1920 is henceforth to apply to benzoyl-morphine, dihydro-oxycodeinone, dihydrocodeinone, and their respective salts, and to any preparation, admixture, and extract containing benzoyl-morphine, dihydro-oxycodeinone, and dihydrocodeinone. This Order in Council is made under Section 8 Subsection (2) of the 1920 Act, whereby His Majesty may apply Part III. to any drug whatever, if it appears that such drug is or is likely to be productive, if improperly used, of ill-effects substantially like those produced by morphine or cocaine.

TUBERCULOSIS IN IRELAND.

(FROM OUR OWN CORRESPONDENT.)

SOME of the communications made to the Congress of the Royal Institute of Public Health held recently in Dublin give interesting information on the subject of tuberculosis in the Irish Free State. Sir William Thompson, formerly Registrar-General of Ireland, showed slides exhibiting the death-rates from tuberculosis in England and Wales, Scotland, and Ireland from 1904 to 1926. The rate for England and Wales had decreased from 1·75 per 1000 living in 1904 to 0·95 in 1926; for Scotland from 2·25 to 1·00; and in Ireland from 2·85 to 1·45. In 1912 tuberculosis came first on the list of causes of death in Ireland with 9400 deaths; in 1926 it came fourth with a little under 7200 deaths. It was generally agreed, Sir William added, that there were eight people suffering from tuberculosis for each death, and one might conclude, therefore, that there were some 16,000 fewer people suffering from tuberculosis than in 1912. Somewhat different figures were given by Mr. E. P. McCarron, Secretary of the Department of Local Government and Public Health. Contrasting the years 1912 and 1927, he found that in the area now comprised in the Irish Free State the number of deaths from tuberculosis in 1912 exceeded those in 1927 by 2600. If both writers are correct then there would appear to be a slight increase in the number of deaths in the area of Northern Ireland. Mr. McCarron added that in respect of the operation during last year of 19 of the approved tuberculosis schemes in the Irish Free State, 1536 tuberculous patients were made fit to resume their ordinary life. He gave these figures as an illustration of the value of wise expenditure in the preservation of the public health. "The blunderer with an axe at public expenditure was a menace to all that was best in our civilisation."

Mr. J. H. Norris, Director of Veterinary Research, Department of Lands and Agriculture, Irish Free State, gave valuable information as to the extent of tuberculosis among cattle in the Irish Free State. There were, he said, no complete or even extensive statistics bearing on the incidence of tuberculosis in dairy cattle in the Irish Free State, but from results of tuberculin tests carried out in various herds it might be assumed that at least 20 per cent. were tuberculous. This evidence was supported by separate statistics kept at the Dublin abattoir. During 1926 23·69 per cent. of cows slaughtered were found to be tuberculous, but of these only 3·17 per cent. showed lesions extensive enough to call for total destruction of the carcass. Only 6·52 of bullocks and 5·59 of heifers were found affected. For some time past mixed samples of milk from herds in various parts of the country had been examined at the Department of Agriculture's veterinary laboratory. Up to June 30th last 391 samples from different herds, containing 3884 cows, or an average of 10 cows in each herd, had been dealt with. All samples, in addition to microscopic examination, were submitted to the biological test, with the result that 18, or 4·60 per cent., were found to contain tubercle bacilli. Positive cases were followed up and dealt with under the Tuberculosis Order.

Correspondence.

"Audi alteram partem."

SMOOTH AND ROUGH VARIANTS OF BACTERIA.

To the Editor of THE LANCET.

SIR,—On the whole I concur in Dr. Arkwrig criticisms, in THE LANCET of August 11th, of letter in the previous number. Especially w I support him in the quest for biological genera tions, without which clear thinking becomes imposs I therefore deeply regret my letter conveyed impression to the contrary. Moreover, the except to such "laws" are of prime importance since often furnish a clue to the relationships betw bacterial races. Doubtless, also, it would lead to confusion had the terms "rough" and "smoo been reserved for the contrasted antigenic and o characters as originally described by Dr. Arkwri Unfortunately, smooth and rough are every words, which so aptly point the antithesis betw two widely distributed types of colony appearance consistence that it is difficult to resist using t for this purpose. The strains of parasites ter *C. diphtheriæ* in my letter, were, in the vast majo of cases, isolated from separate hosts, or the s host at different times; only a few strains derived from a common parent strain during t laboratory existence. Surgeon-Commander Pa only describes the laboratory side of the investigat referred to. The work was an attempt to find what variations took place in certain "non-speci characters of a group of bacteria all of which enough "specific" characters to satisfy my con of *C. diphtheriæ*. The results indicated that du their existence in their natural habitat, the hu throat, this group varied widely in compositio different times and places. As Dr. Arkwright t points out, any value this work may have dep on the meaning given to *C. diphtheriæ*. Perha brief attempt to explain what I do mean may slight extent indicate the relationship between species-concept and variation as applied to bact I believe it to be unwise at the present time to d too rigidly any bacterial species. As a working h thesis an organism must have certain stable definite criteria before it is assigned to a " ventional type species." As facts accumulate it be found advisable to add or subtract criteria these which determine the "type species," in c to exclude or include certain strains of bacteria. example, in the Greenwich investigations a bacte had to possess the following attributes before it diagnosed as *C. diphtheriæ*. The organism ferment glucose but not saccharose, grow aerobi on congulated serum without liquefying it, and non-chromogenic colonies. Smears from culture suitable age on solid serum had to show Gram-posi Neisser-positive, pleomorphic bacilli. It is evi from Dr. Arkwright's letter, that although I *feel* the above definition is the most practicable to round, yet he *feels* some reference to toxin produc is essential in order to identify an organism *C. diphtheriæ*—i.e., should a culture of an organ otherwise qualified for inclusion in the species, pro no diphtheria toxin, it must be known that ancestors were toxigenic before it can be na *C. diphtheriæ*. It may be taken as now defin established that many toxigenic races of *C. theriæ* are able to throw off avirulent variants. B this was generally accepted, many bacteriolo considered that *all* avirulent bacilli were sp distinct from virulent diphtheria bacilli. Such opinion is no longer tenable, and even if there sh be "pure lines" of bacilli, possessing the cri given above, whose ancestors never have and w

cendants never will produce diphtheria toxin, re is no means, so far as I know, of distinguishing m from other races similar in all respects except t their recent ancestors were known to have been igenic—i.e., to have possessed a different antigenic ke up. As the word indicates, antigenic characters a parasite imply reactions in the host and hence are paramount importance in medicine. In spite of s fact, it is debatable if antigenic qualities are in eral sufficiently stable for differentiation of pecies," however useful they may be in describing species, types, races, varieties, and special strains hin the species.

For these reasons I personally dislike including any erence to toxigenicity in the description of *C. diphiæ* as a "species"; but the subject is full of iculties of which this correspondence is only able give a hint. However, Dr. Arkwright's letter strates clearly one point of practical importance—t, until there is a universally used standard terial nomenclature, where an author refers to a division of the bacteria, he must take care that s possible for others to understand exactly what he ans. I plead guilty to not having done so in my vious letter.

I am, Sir, yours faithfully,

SHELDON F. DUDLEY.

oyal Naval College, Greenwich, S.E., August 11th, 1928.

'APWORTH COLONY AND SANATORIUM TREATMENT.

To the Editor of THE LANCET.

IR,—Several daily papers represented at the recent blin Congress have been devoting leading articles the above; and, so far as they help Dr. Varrier-es's cause, they will do nothing but good. Unfor-ately, however, they give the impression that atorium treatment has been a failure, a statement ch is at most a half-truth, and much to be deplored. he immediate results of sanatorium treatment are risingly good; favourable cases are restored to lth, and many unfavourable ones are much roved. In the most favourable, the good results permanent; but, unfortunately, four-fifths of se applying for treatment have already passed most favourable stage, or for other reasons are likely to make a complete recovery, whatever treatment. In such cases the results of sana-um treatment are conditional, and relapses happen he quarters are unsatisfactory, the conditions of are unhealthy, or the rules learnt in the sana-um forgotten or ignored. To blame the methods reatment because the after-conditions are not sfied is not logical. One of these after-conditions he possibility of earning an adequate wage under thy conditions. Another is to permit of rest he open-air if symptoms arise which call for it. s a great merit of Dr. Varrier-Jones's arrange-ts at Papworth that these three essentials are rided. His methods are not a substitute for torium methods (for there is no substitute), they are a valuable extension. Many of his ates have had some treatment in a sanatorium; any of them receives a similar treatment in the ny whenever he needs it.

rom the earliest days of sanatorium propaganda as clearly stated that the sanatorium is only one —though an essential one—in the chain of treat-t. So long as the fear of infection prevents the torium patient from obtaining remunerative loyment under suitable conditions, the need for nies like Papworth, or for special workshops as cated by the late Dr. F. S. Tinker, will be urgent; they are not, and cannot be, a substitute for the torium, which combines advantages in the same as a hospital for other ailments.

I am, Sir, yours faithfully,

F. R. WALTERS.

rnham, Surrey, August 25th, 1928.

THE LATER RESULTS OF PARTIAL GASTRECTOMY FOR GASTRIC AND DUODENAL ULCER.

To the Editor of THE LANCET.

SIR,—A study of the figures relating to chronic gastric and duodenal ulcer given by Mr. Norman Lake in his paper on the "Later Results of Partial Gastrectomy" in THE LANCET of August 11th shows that (1) gastro-enterostomy was *unsatisfactory in 36 per cent.* of 61 cases, but there was no mortality; (2) partial gastrectomy was unsatisfactory in only 2·5 per cent. of 51 cases, but there was a *mortality of 9 per cent.* (5 out of 56), which is greater than the risk of malignant degeneration.

These are the "later" results, but experience shows that the "last" results—i.e., after an interval of ten years or more instead of five years or less, would give a much greater number of unsatisfactory results, especially in view of the fact that Mr. Lake allows his patients to eat whatever they like. In the German and American clinics, in which partial gastrectomy has been the routine surgical treatment of ulcer for ten years, so many anastomotic ulcers have followed the operations recommended by Mr. Lake that nothing less than excision of four-fifths of the stomach is now performed. This would presumably have a still higher mortality, and we shall have to wait another ten years before we know how often it is followed by jejunal ulcer. Then I expect complete gastrectomy will become the operation of choice, for nothing short of this will produce achylia, as Klein has shown that when the secretion of appetite juice is stimulated by tasting or seeing food, but nothing is swallowed, free acid appears in the small portion of the stomach still remaining after subtotal gastrectomy.

It is clear that, *if* Mr. Lake's results can be taken as typical: (1) gastro-enterostomy is unjustifiable except for pyloric obstruction because of the 36 per cent. unsatisfactory results; and (2) partial gastrectomy is unjustifiable because of the high mortality.

An interesting commentary on Mr. Lake's paper is the fact that since 1921 we have had at New Lodge Clinic 37 patients suffering from gastric ulcer, 165 from duodenal ulcer, and no less than 67 from the ill-results of gastro-enterostomy or partial gastrectomy, performed in most instances for ulcer. Our experience shows that gastro-enterostomy is the commonest gastric disorder to-day, and undoing gastro-enterostomies is the gastric operation we now most frequently recommend.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, August 15th, 1928.

To the Editor of THE LANCET.

SIR,—I have read with interest Mr. Lake's paper published in your issue of August 11th; there is a good deal in it, however, which does not coincide with my own experience. An extensive inquiry into the after-results of a short-circuiting operation for duodenal ulcer show that these are at least as good as those following any surgical procedure in the abdomen. I am not concerned here with the respective merits of gastro-duodenostomy and gastro-jejunostomy; and for the sake of convenience will hereafter refer to both as gastro-enterostomy.

I am sure that surgeons who are constantly and fully carrying out the technique involved in the operation of gastro-enterostomy will regard Mr. Lake's figure of 36 per cent. unsatisfactory results as much too high. Indeed, such a figure is undoubtedly a very strong reason for seeking some other operative procedure. In my experience the unsatisfactory results are not more than 10 per cent., and in many of these the symptoms are so slight and evanescent that the cases should be included under Mr. Lake's heading of "satisfactory." Again, it is not clear on reading this paper how many gastrectomies were done for duodenal ulcer and how

many for gastric ulcer. It is essential to differentiate, for in many respects the two diseases are very unlike. The type of patient is not the same, gastric ulcer makes the patient much more ill as a rule, and duodenal ulcer is virtually never the precursor of malignant disease. It is a debatable point as to how often carcinoma becomes grafted on to gastric ulcer, but I think most surgeons allow that it happens sufficiently often to cause the possibility of any such change to pass through their minds on most of the occasions on which they deal with a gastric ulcer. The difference between the two types of ulcer (or perhaps one should say the types of patient) has a vital bearing on the statistics of anastomotic ulcer following gastrectomy. I have seen three cases where such an ulcer had formed after partial gastrectomy had been done for jejunal ulcer in which gastro-enterostomy had been done previously for duodenal ulcer; I have Sir Berkeley Moynihan's permission to say that he has had 12 such cases sent to him, and that he has never seen an anastomotic ulcer develop after a primary gastrectomy for gastric ulcer. Mr. Lake's explanation, that too little of the stomach was removed (that is to say, not all of the acid secreting part) does not apply to these cases.

Because of the difficulty of dealing directly with ulcers on the posterior surface of the duodenum, eroding the pancreas and causing marked deformity, I should regard these as the ulcers to be treated by gastrectomy, if this operation were ever necessary for duodenal ulcer; but gastro-enterostomy is very successful in these cases and the mortality is less than 1 per cent. I venture to say that in a series of this type gastrectomy would show a very much bigger mortality, and I presume this is the kind of ulcer Mr. Pannett has in mind when he finds it necessary to insert in his book on gastro-duodenal ulceration some paragraphs dealing with injury to the bile and pancreatic ducts as a complication which is observed in a certain percentage of cases of resection.

It is a great mistake to think that having performed the operation of gastro-enterostomy the business is finished. It is essential to deal with the ulcer itself at the time, and to treat the patient medically for long afterwards. I would suggest that the failure to take these two points into consideration in compiling statistics goes far to explain the high figures of unsatisfactory results sometimes given. This does not condemn gastro-enterostomy, or show the necessity to substitute gastrectomy; it is a reflection on the vision of the surgeon, for after all there is, or may be, still an ulcer present, and the operation only goes part of the way in promoting the patient's complete recovery.

I think if Mr. Lake could show that gastro-enterostomy gave the high percentage of unsatisfactory results which he quotes, in spite of a full measure of complementary treatment before, at, and after the operation, he would convince his readers that there were sound grounds for advocating gastrectomy for duodenal ulcer—even though it is followed by a higher mortality, and carries with it the risk of anastomotic ulceration, a risk which may prove to be as great as that after gastro-enterostomy, if no more.—I am, Sir, yours faithfully,

E. R. FLINT, F.R.C.S. Eng.

Leeds, August 15th, 1928.

THE HEART AND CIRCULATION IN BERI-BERI.

To the Editor of THE LANCET.

SIR,—May I refer Dr. Sutherland to the *Dublin Journal of Medical Science* for October, 1916, in which I draw attention to the negative pressure existing in the pericardium of a healthy person, and its tendency to disappear from the pericardia of persons in ill-health, especially those with serous effusion in the large cavities. This negative pressure results in a suction action whereby the pericardial fluid is kept at an equal thickness all over the surface of the heart and acts as a support to the working organ. A removal of that support affects the weaker-w right ventricle at an earlier stage than the left. I suggested the formula $F=(P+I)\div(T+S)$ w F=fibrillation, P=pressure, I=impulses, T=t and S=support; from which it is easy to see if tone or support or both be diminished the tend to fibrillation is increased. In beri-beri effusion oc into the serous cavities, the general feebleness of circulation implies that tone is less, conseque heart failure sets in. Prof. Wenckebach sug the existence of a law of circulatory correla between the right and left heart, working along si mechanical lines. Does my formula help him in contention?

I am, Sir, yours faithfully,

G. ARBOUR STEPHENS,

Consulting Cardiologist, King Edward VII. We National Memorial.

Swansea, August 18th, 1928.

THE VITAMIN A CONTENT OF COD-LIVE OILS.

To the Editor of THE LANCET.

SIR,—In your issue of June 30th (p. 1353) J. C. Drummond attempts to counter statem made in an article published in the *Anglo-Norw Trade Journal* for May, 1928, which is based information which I have given the editor of journal. Drummond's reply does not touch the crux of the matter, and is therefore unsatisfac As previous articles regarding this matter appeared some years ago, a short résumé is neces

1. In 1924 Prof. Drummond (University Co London), jointly with Dr. S. S. Zilva (the I Institute, London) and Dr. Graham (The Fish Laboratory, Lowestoft), published in the *Bioche Journal* (1924, XVIII., 178) a paper entitled: Relation of the Vitamin A Potency of the Live to the Sexual Condition and Age of the Cod this very searching work they particularly tr the question whether the spawning of the cod any influence on the vitamin content of the Repeatedly, and in a most definite way, it is s in the article referred to that no such influence be demonstrated. For example: regarding results of the four series of tests of cod from I borough and Scarborough during the montl January to June, it is stated that "even the oils from spent cod in March fish, which must spawned just before being caught, and which no time to recuperate, did not deviate in po from the oils of fish before spawning, and se months after spawning and consequently recuperation." The paper ends up with the follo summary: "The sexual condition and age o cod do not influence the vitamin A potency o liver oil." In 1924 I myself carried out si investigations, and came to the same conclusion in view of the paper in the *Biochemical Jour* considered any publication of my findings superfl

2. In 1925 Prof. Drummond published in LANCET (Sept. 26th, p. 679) a paper in which, wi producing any fresh data, he says, with rega oils produced in the important fishing distri Lofoten (Norway), that during spawning th becomes poor in vitamins and contains only one- to one-fifth of the vitamin potency of that from other places (Finmarken and Newfound where the fisheries do not take place durin spawning period. The reason apparently being when the fish "are practically starving durin spawning period, and are at the same time transf much fat and vitamin to the reproductive cell livers yield an almost white oil of relatively potency." This is exactly opposite to the fi of Prof. Drummond and his collaborators in about the fish in this condition it is here said "the relative potency of the residual liver however, not effected."

Drummond's paper of 1925 has during these years ved as the basis for an exceedingly intense vertising of Newfoundland cod-liver oil, at the pense of the Norwegian oil and at great economic s to the latter.

3. It was not until several months later that I came aware of Drummond's article in THE LANCET Sept. 26th, 1925, and I thereupon wrote a rejoinder ich appeared in your issue of Feb. 6th, 1926 320). Therein I expressed surprise that the Prof. ummond of 1925 should contradict the Prof. ummond (and his colleagues) of 1924. My paper s couched in the most moderate terms. I sent a py of it to Drummond, and although it appeared cessary that he should furnish some explanation, sent me no answer.

4. On the other hand, a reply was made by . Zilva, who had previously collaborated with of. Drummond. This reply is now made use of such a way by Drummond in your issue of June 30th 1353) that the reader who has not kept fully in ich with developments may get the impression that va supported Drummond. I do not believe others l agree with this interpretation. Zilva's reply ves nothing to be desired in the way of explicitness :

> As I did not see Prof. Drummond's article until it peared in print I do not hold myself responsible for rything stated therein. Prof. Poulsson is quite right asserting that the sexual condition of the cod during wning has no bearing upon the activity of the oil, as shown by my colleagues and myself, and I feel gratified t this work has been confirmed by our Norwegian eague."

Prof. Drummond must be in a most unhappy frame mind when he accepts this severe correction hout a word of protest.

t appeared inevitable that Prof. Drummond should this juncture explain himself, but no such explana- n has been made, not even in his last letter. tead of explaining upon what basis in 1925 he ies results achieved by himself and his colleagues 1924, he devotes a lot of space to treating other jects not relevant to the present issue. For mple, a comparison is made between the biological l colorimetric tests, obviously in order to get an portunity to point out that my tests of certain ples of cod-liver oil had been carried out according a defective method. In this connexion I will tent myself with pointing out that these assays l partly been completed already in 1923; the proved and now applicable method was described Steenbock in 1924.

ummarising the above, we find ourselves faced h an instance of an author contradicting himself l his colleagues without communicating with them e of them subsequently denying responsibility), hout producing new data, and without offering explanation. A situation of this kind is paralleled in scientific discussion, and the situation by no means clarified by Drummond's last letter, ept in so far as he has now abandoned the con- tion which formed the chief basis of his paper in E LANCET of Sept. 26th, 1925—namely, that the ual condition of the cod during the spawning od influences the vitamin content of the liver

I am, Sir, yours faithfully,

slo. E. POULSSON.

INSTRUCTION IN PSYCHIATRY.

To the Editor of THE LANCET.

SIR,—I should like in the first place to thank you for the kindly notice of my book on "Mental Disorders" in your issue of July 21st. My object in writing to you now is to comment on Dr. Estelle Cole's letter in your issue of August 11th. I hope that your review will be approved not only by "many of the older school of psychiatry," but also by those of some at least of the newer schools who realise the inadequate condition of much of modern psychological teaching regarding, for example, the psychoneuroses. So long as such a short period of time is allotted in the medical curriculum for the teaching of psychiatry in general, it seems to me that it would be unwise to employ more than a modicum of it in dealing with contentious psychological matters. When there is something approaching a settled doctrine I shall be only too glad to set it forth for those students and others who may care to read what I write. In conclusion, I find myself in complete agreement with what you say in your note that "so important and difficult a subject should be properly taught or left alone." It seems to me that there is a good deal of modern pseudo-psychology—or pseudo-psychopathology—which is not properly taught, but which is improperly practised.

I am, Sir, yours faithfully,

Wimereux, August 20th, 1928. HUBERT J. NORMAN.

"FUSSING OVER CANCER."

To the Editor of THE LANCET.

SIR,—Your correspondent "D.P.H.," in the course of an excellent letter, remarks that it is really a truism to say that "the earlier cancer is detected the better are the patient's chances of recovery." Having made this uncontroversial statement, he goes on to ask: "Why is there a certain hesitancy . . . in launching educational campaigns with regard to cancer?" and the inference would seem to be that "cancer campaigns throughout the world" have neglected this very useful part of what should be one of their primary activities. In order to attempt to prevent this inference being accepted as the whole truth of the matter, may I be allowed to draw the attention of your readers to some of the educational work undertaken by the Yorkshire Council of the British Empire Cancer Campaign?

Shortly after the Yorkshire Council was created, our leader, Sir Berkeley Moynihan, recognising that the education of the public was of prime importance, proposed that a propaganda subcommittee should be formed and financed. This was done, and the funds placed at its disposal were considerable in amount and were mainly derived from donations given by Insurance and Panel committees in the County. This subcommittee has done a great deal of work. It has issued a very comprehensive little book entitled "Notes on Cancer," prepared under the direction of the Medical and Scientific Committee of the Yorkshire Council. Free copies of this book have been sent to all practitioners in the county and many have been sent, by request, to almost all parts of the Empire. Any practitioner requiring the book may have it on application to our Secretary, at 47, Park-square, Leeds. The subcommittee has organised several courses of post-graduate lectures to practitioners by eminent authorities, the list of lecturers including the names of such well-known men as Sir Berkeley Moynihan, Prof. G. E. Gask, Prof. Grey Turner, Dr. Major Greenwood, and Prof. Sampson Handley. Most of these lectures have been very largely attended, and there is a demand for further courses which the subcommittee hopes shortly to be able to meet.

Having, in the above ways, attempted to assist practitioners by placing before them the latest available information, the subcommittee directed its attention to an effort to educate the public. It first succeeded in obtaining the services of a competent woman doctor who was well fitted to place facts before individuals which it felt they ought to know. It then organised a series of public demonstrations, called—for want of a better name—"cancer exhibitions." Each exhibition visits a selected town and is open to the public for, usually, one week. Various statistics, showing the number of deaths arising from cancer in different parts of the body are exhibited in graphical form. Large quantities of leaflets are used and visitors urged to take them home and show them to their friends. Information

on various questions of health is given. Lectures by medical men and women of standing are delivered, and each day a local doctor gives a short talk, emphasising the necessity for early advice and treatment in all cases where the disease may be suspected. The woman demonstrator has personal interviews with visitors throughout each day and the burthen of her story is: "If you have anything wrong—or if you *fear* you have anything wrong—don't go on anxiously worrying, but consult your doctor and ask him to examine you and advise." These exhibitions have been attended by marked success. Thousands of people have visited them, and excellent reports of the lectures and addresses have been given in the public press. They are not easy to organise, for the difficulty in making them attractive to the public, whilst at the same time excluding all "gruesome" details is a very real one. None the less the subcommittee is very satisfied with the results. The deplorable experience of Dr. Stanley Reimann, as given in "D.P.H.'s" letter, has not been ours! When our work began I think most lay people agreed that a diagnosis of cancer—no matter where situated or how early or late it had been recognised—was tantamount to a sentence of death. This is not so now. The facts that some 50,000 people die annually from cancer in England and Wales; that getting on for 20,000 of these cases originally arise from superficial—and therefore get-at-able areas; that an enormous percentage of early cases have been shown by fully confirmed hospital reports to be alive 10 years after treatment, constitute, when proclaimed, a "message of hope" which the public is not slow in appreciating. Evidence supplied by surgeons and general practitioners in our county convinces us of this.

The fears of "frightening people to death," of "creating a nation of neurasthenics," do not impress the members of our Council. Our leader's happy phrase—"frightening them to *life*"—appeals to us more strongly, and it is a long time since I read so excellently logical an exposure of the futility of commonly used objections as that given in the letter of "D.P.H."

I am, Sir, yours faithfully,

G. B. HILLMAN,

Chairman, Medical Propaganda Subcommittee, Yorkshire Council, British Empire Cancer Campaign.

Wakefield, August 18th, 1928.

OSTEOCLASTOMA.

To the Editor of THE LANCET.

SIR,—I should be much obliged if you will correct an error which appears in THE LANCET of July 28th (p. 183) in the report of the proceedings of the recent International Conference on Cancer. In the discussion on bone sarcoma I spoke in favour of the view that the so-called giant-celled tumour or myeloid sarcoma is derived from the fibrous-tissue framework of bone and that the giant cells are osteoclastic (not osteoblastic) in nature. Osteoclastoma (not osteoblastoma) was suggested as a better name for this tumour than any of those at present in use, combining, as it does, brevity with precision of meaning.

I am, Sir, yours faithfully,

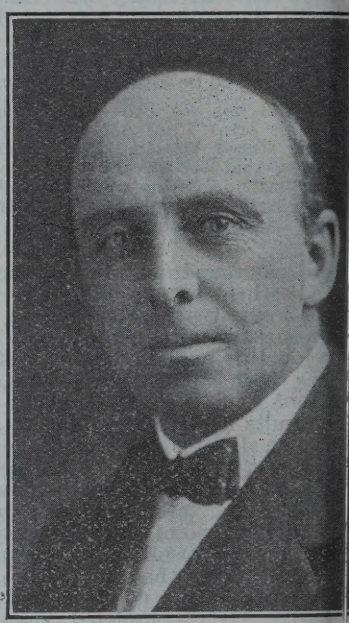
Leeds, August 15th, 1928. M. J. STEWART.

PAYMENT FOR MOTOR ACCIDENT PATIENTS.—The governors of Folkestone Royal Victoria Hospital last week adopted the following resolution: "In cases provisionally admitted by the resident medical officer or by the matron for immediate treatment which has become obligatory as the result of a motor accident, each patient admitted shall pay for treatment at the rate of 11s. 4*d.* per day, subject, however, to the committee deciding subsequently that these charges be increased, reduced, or remitted." The resolution was the result of correspondence with the Central Bureau of Hospital Information.

Obituary.

WILLIAM SMITH SYME, M.D. EDIN., F.R.F.P.S. GLASG.

Mr. Syme, who died suddenly on August 1 when on a holiday in North Wales, was well kn in Cumberland and south-west Scotland as a speci and writer on diseases of the nose, throat, and Born in Harbour Grace, Newfoundland, in 187 was at an early age sent to school at Blair L and continued his medical studies at Edinbu where he qualified M.B., C.M. in 1891. He went as assistant to Dr. Charles Wilson, of Cr before starting general practice himself at Gamlin Cambs, where he remained till 1902. He had alw enjoyed the life of the country and at that tim joined in the field sports of all kinds, being cap of the cricket team for some years. His return to Scotland was actuated by the desire to develop the more scientific professional side of his work, and after attending the clinics of Dr. Thomas Barr at the Ear Hospital and Dr. J. W. Downie at the Western Infirmary, and working on the former's staff, he decided to specialise in ear, nose and throat work, and in 1904 began consulting work in this specialty in Carlisle, and some years later in Dumfries. In 1913 the course at the Western Me School was recognised by the University; in Mr. Syme was appointed surgeon to the Ear, and Throat Hospital, and three years later to Nose and Throat Western Infirmary. In the year he became lecturer on diseases of the th later adding appointments and a lectureship in surgery to his other duties.



MR. W. S. SYME.

Photo by Annan, G

Mr. Syme was one of the founders of the Sco Otological and Laryngological Society, and for n years its hon. secretary and treasurer. He w ready and accurate writer on clinical subjects most considerable literary work being a hand for students and practitioners, published in 192 which a new edition has recently appeared. aim in this book was especially to stimulate interest of students in a subject likely to co them very closely, immediately on entering ge practice. His oral teaching will be missed by Gla students who found in him the embodiment of g humoured energy, and one who always showe active interest in athletics, while the nursing were pleasantly aware of the uniform kindness courtesy with which he treated both patients and relatives. His devotion to duty and the heavy of detailed professional work are regarded by friends as contributory to his early death. Few

said, held such a place in the esteem and affection heir colleagues.

Ir. Syme married in 1895 a daughter of Thomas sley, J.P., of Greysouthen, Cumberland, and is rived by his wife, two sons, and four daughters.

MARY LAUCHLINE McNEILL, M.B. GLASG.

EWS has been received from Kamali, Africa, of death of Dr. Mary McNeill, on June 10th, from hoid fever at Jinga Hospital. Dr. McNeill was n in 1874 at Holm in the Orkney Islands, eldest ghter of the Rev. Daniel McNeill, M.D. She went school at Fochabers, studied music and languages Germany and Switzerland, and later became a lical student at Queen Margaret College, Glasgow, re she graduated in 1905. She then returned to ney and practised there until 1914, when she t to Leicester to relieve her brother for service n the R.A.M.C. In 1916 Dr. McNeill held the ointment of resident physician in the Leicester er Hospital for several months until she joined staff of the Scottish Women's Hospital in Salonika. remained there until early in 1919, when moved with the hospital to Belgrade. In the mn of the same year she went to Tiberias in stine to the U.F. Medical Mission under Dr. ance, and thence to the Central Provinces, India, l 1921. After a short holiday at home she became ember of the Church of Rome and joined the olic African Mission, first at Kampala, Uganda; rly she worked single-handed with three Frann Sisters at a remote station in Kamali. She looking forward to coming home on leave in ember.

of. A. L. McIlroy writes: "Those who knew Mary McNeill loved her for her upright character, unselfish life, and her devotion to her family. mysticism and joy in living was a source of ler to her friends. She took a great interest in ature and art, and had a most marked gift for ng and for poetry. She was a loyal colleague, always upheld the administration of those under n she worked. Dr. McNeill never lost her hful interest in people and places. She had elled extensively, had absorbed new ideas and e friends wherever she journeyed. Her passing eft a great gap in the hearts of her friends."

YAL MEDICAL BENEVOLENT FUND.—At the last ng of the Committee 50 applications for assistance considered and £825 5*s.* voted to 45 cases. Considera- f the following notes on a few of the applicants helped how how sad some of the cases are and how urgent is eed of help, yet unfortunately the grant was small. und appeals for subscriptions to enable it to make more ate grants. Subscriptions and donations should be o the hon. treasurer, 11, Chandos-street, Cavendish e, W. 1.

.C.S. Edin., aged 74, married; wife aged 72. The husband pletely broken down in health and is quite unfit to do any f work. This old couple have a total income of £82 a year, up of Old Age Pension £52 and Epsom Pension £30. As ent is £26, there remains only £56 for food and clothes. £40, thus raising their income to £122 a year.

., aged 75, bedridden. Has no private means, but was earn a little last year from literary work. Voted £40.

ow, aged 80, of M.D. Bedridden and suffers from cerebral iginal attacks, requires nursing day and night. Her only is £50 being rent from a property which she has been to sell. Her two children have done all in their power to ad have contributed £42 a year. Voted £40.

ow, aged 73, of L.R.C.P. On the death of her husband 8 her house was sold and the proceeds went to pay off g debts, leaving the widow only £370 as capital. She ceipt of Old Age Pension. Her relations have given some al assistance this year but cannot continue to do so. £26.

ow, aged 52, of M.B. Since the death of her husband pported herself and her invalid son by taking in paying s but owing to ill-health (diabetes) has been unable to ests during the last 12 months. Her son has a congenital with marked cyanosis. Income during past year was nents £7 10*s.* and from a paying guest £6. Voted £26. nd is trying to get other charities to assist in this very e.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates satisfied the examiners in the undermentioned subjects:—

Surgery.—J. P. Collinson, Sheffield and London Hosp.; H. B. Blaker, St. Mary's Hosp.; E. C. Gross, Guy's Hosp.; I. G. Hardinge, Charing Cross Hosp.; G. L. Johnson, Columbia Univ., U.S.A.; C. K. McCoan, St. Mary's Hosp.; and C. F. C. White, Guy's Hosp.

Medicine.—T. A. Barnabas, Bristol; C. M. Brooks, Durham; J. S. Bury, Manchester; A. E. Gibbs, London Hosp.; K. Girgis, Manchester and Charing Cross Hosp.; I. G. Hardinge, Charing Cross Hosp.; H. H. Jackson, Manchester and Charing Cross Hosp.; G. L. Johnson, Columbia Univ. U.S.A.; H. C. Johnson, Minnesota, U.S.A.; J. H. Johnston and G. L. McDermott, St. Bart.'s Hosp.; M. T. Y. Selim, Liverpool; and H. D. K. Wright, St. Bart.'s Hosp.

Forensic Medicine.—N. Das, London Hosp.; E. C. Gross, Guy's Hosp.; I. G. Hardinge, Charing Cross Hosp.; A. H. Hennessy, Adelaide and London Hosp.; G. L. Johnson, Columbia Univ., U.S.A.; H. C. Johnson and K. R. Lundeberg, Minnesota, U.S.A.; C. P. Madden, St. Bart.'s Hosp.; S. M. Rahman, Calcutta and Middlesex Hosp.; M. T. Y. Selim, Liverpool; and H. D. K. Wright, St. Bart.'s Hosp.

Midwifery.—C. M. Brooks, Durham; H. C. Clifford-Smith, Charing Cross Hosp.; W. A. A. Collington, Guy's Hosp.; J. P. Collinson, Sheffield and London Hosp.; F. W. Crossley-Holland, St. Bart.'s Hosp.; L. P. Gregory, Bristol; I. G. Hardinge, Charing Cross Hosp.; A. H. Hennessy, Adelaide and London Hosp.; G. L. Johnson, Columbia Univ., U.S.A.; H. C. Johnson and K. R. Lundeberg, Minnesota, U.S.A.; R. Perkins, St. Bart.'s Hosp.; and T. A. P. Proctor, Birmingham.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: H. B. Blaker, H. C. Clifford-Smith, J. P. Collinson, I. G. Hardinge, A. H. Hennessy, G. L. Johnson, G. L. McDermott, S. M. Rahman, M. T. Y. Selim, and H. D. K. Wright.

DERMATITIS AMONG BAKERS.—At the Eighteenth Annual Congress of the Amalgamated Union of Operative Bakers and Confectioners held at Cardiff on August 20th, attention was called by the general secretary of the union (Mr. W. Anfield) to the alarming spread of dermatitis among bakers throughout the country. He asserted that there is a conspiracy of silence on the part of men suffering from the disease and also on the part of their employers. He believed that for every one man reported to be suffering from this disease there were three others unreported. It was suggested that since 1918 and 1919 something had been introduced into the raw material used by bakers which had caused a greater spread of this disease, and that the sole sufferers are the operative bakers. A resolution was passed stating that the conference viewed with alarm the spread of dermatitis among members of the union, and urged the Executive Committee to spare no expense in the matter, and to call for the assistance of the Government department together with the Master Bakers' Association and the millers and the medical profession.

THE LONDON HOSPITAL.—In 1927 the annual report records there were 16,840 in-patients who stayed, on an average, 15–19 days and cost £11 3*s.* 6*d.* each. New out-patients to the number of 114,509 made 567,525 attendances at a cost of 12*s.* each. The total ordinary income increased from £234,088 to £263,546, while ordinary expenditure fell from £262,900 to £250,419. The year's legacies totalled £51,315, nearly double the average.

CONTRIBUTIONS TO HOSPITALS FROM DOCKERS.—More than 10,000 dockers have agreed in writing to contribute to the Merseyside Voluntary Hospitals Penny-in-the-Pound scheme.—During the year ended on June 30th last Devonport Dockyard and its allied establishments, by means of a similar scheme, raised £5136, making a total for the last five years of £20,891.

MANCHESTER GUARDIANS AND CANCER FUND.—The Manchester board of guardians at its meeting on August 22nd again discussed the guardians' contribution of £1000 to the Lancashire, Cheshire, and North Wales Council of the British Empire Cancer Campaign, as the result of a letter from the Minister of Health intimating his inability to sanction the contribution. It was stated that the Minister was "unable to regard so considerable a donation to a fund of this kind as being within the spirit and intention of Section 36 of the Poor-law Act, 1927." He was, however, prepared to consider favourably applications from the guardians to subscribe reasonable amounts to the funds of the hospitals undertaking the treatment of cancer, in which persons receiving relief from the guardians are having, or are to have, assistance in cases of necessity.

MATERNITY HOSPITAL FOR SOUTHPORT.—The Southport Health Committee has accepted the offer of Miss Christiana Hartley, a former mayor of the town, to build a new maternity hospital. The present building was a temporary soldiers' hospital and last year, out of 1000 births in Southport, 300 took place within it. The new institution will be adjacent to the infirmary and will correspond, in design and material, with its main block.

THE LATE DR. S. W. GRIFFITH.—Samuel Wilbraham Griffith, of the Hermitage, Pwllheli, died suddenly on August 24th, aged 72. He began his medical studies in Dublin and continued them in Edinburgh, where he qualified L.R.C.P. and L.R.C.S. in 1884. He was one of the best-known medical practitioners in North Wales, a J.P. of Carnarvonshire, and senior magistrate of the shire, having officiated in the Pwllheli Court for nearly 40 years.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—This hospital, which has been under construction on its new site in Broad-street, Holborn, since November, 1926, is now completed and will be open for the admission of in-patients on Monday, Sept. 3rd. The out-patient and casualty departments were opened last Easter. In addition to the public wards, there are 14 single private rooms, which will be available in the autumn. The new hospital has cost, including the freehold site, about £150,000, towards which nearly £100,000 has been raised by the sale of the old site in King William-street, Strand, and by public appeal. The remaining £50,000 has yet to be found.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.1.

MONDAY, Sept. 3rd, to Saturday, Sept. 8th.—QUEEN MARY'S HOSPITAL, Stratford, E. Second week of Intensive Course in Medicine, Surgery and the Specialties. Syllabus on application to the Secretary.

Appointments.

BRECHIN, F., M.B., B.Ch. Glasg., D.P.H., has been appointed Medical Officer of Health, Renfrew.

DAVIDSON, M., M.D. Oxf., F.R.C.P. Lond., Consulting Physician to St. Luke's Hospital, Chelsea.

DUNSCOMBE, CLEMENT, M.B., B.Chir. Camb., D.P.H. Oxf., Medical Officer of Health for Mansfield Woodhouse, Notts., and Assistant School Medical Officer, Nottinghamshire County Council.

LOBBAN, G. M. D., M.B., Ch.B. Leeds, Assistant Schools Medical Officer, Oldham.

MITCHELL, L. M. V., M.B., Ch.B. Edin., to be one of the Medical Referees under the Workmen's Compensation Act, 1925, for Inverness (Mainland) District of the Sheriffdom of Inverness, Elgin, and Nairn.

ROWNTREE, S. J., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for Islington.

STEVENS, W. G., L.R.C.P., L.R.C.S. Edin., Consultant Medical Officer of Health, Renfrew.

THOMSON, H. W., M.D. Glasg., a Specialist Medical Referee under the Workmen's Compensation Act for Ophthalmic Cases in the Sheriffdom of Lanark.

Surgeons under the Factory and Workshop Acts: BELLIS, T. M.B., Ch.B. Liverp. (Llanfairfechan); BRUCE, D. W. (Chagford, Devon); ELLIS, G. E., M.B., B.S. Lond. (Bourton, Dorset).

Vacancies.

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

All Saints' Hospital, 49–55, Vauxhall Bridge-road, S.W.—H.S. At rate of £150.

Birmingham and Midland Eye Hospital, Church-street.—H.S. £110.

Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200.

Brighton Education Committee.—Asst. Sch. M.O. £600.

Cairo, Egyptian University.—Faculty of Medicine: Professor of Forensic Medicine. L.E. 1500. Also Prof. of Clin. Surg., &c.

Canterbury, Kent and Canterbury Hospital.—3rd Res. M.O. At rate of £125.

Cheltenham Borough.—M.O.H. and Sch. M.O. £850.

Chester Royal Infirmary.—H.P. £120.

Croydon General Hospital.—Cas. H.S. £125.

Dorchester, Dorset County Hospital.—H.S. At rate of £120.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Eastbourne, Princess Alice Memorial Hospital.—Jun. H.S. At rate of £100.

Exeter, Wonford House.—Deputy Medical Supt.

Hull, City and County of Kingston-upon-Hull.—Asst. M. £600.

Leeds City Hospitals.—1st Asst. Res. M.O. £450.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

Lowestoft, St. Luke's Hospital.—Med. Supt. £800.

Manchester, Ancoats Hospital.—H.S. At rate of £100.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—M.O. At rate of £125.

Manchester, Monsall Hospital for Infectious Diseases.—Se Asst. M.O. Also Jun. M.O. At rate of £375 and respectively.

Manchester, Royal Children's Hospital, Gartside-street.—M.O. At rate of £150.

Manchester, Royal Children's Hospital, Pendlebury.—Res. Officer. At rate of £125.

Metropolitan Ear, Nose and Throat Hospital, Fitzroy-square, H.S. £150.

Miller General Hospital for South-East London, Greenwich-S.E.—Pathologist. £600. Also H.P. At rate of £12

National Hospital for Diseases of the Heart, Westmoreland-s W.—Res. M.O. At rate of £150.

Northampton General Hospital.—H.P., H.S., and two Asst. H Each at rate of £150.

Patna Medical College.—Prof. of Physiology. Rupees 1200.

Plymouth, Homœopathic and General Hospital.—H.S. At ra £100.

Prince of Wales's General Hospital, Tottenham, N.—Anæsthetist. At rate of £120.

Queen Charlotte's Maternity Hospital, Marylebone-road, N. Asst. Res. M.O. At rate of £80.

St. George's Hospital Medical School, S.W.—Pathologist Lecturer in Pathology. £575.

St. Mary's Hospital, W.—Asst. Pathological Chemist. £30

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Ga W.C.—H.S. At rate of £75.

Salford Municipal Maternity Home and Babies' Hospital, Se terrace, Pendleton.—Asst. Maternity and Child W M.O. £600.

Salisbury General Infirmary.—H.S. £150.

Shrewsbury, Royal Salop Infirmary.—Res. H.S. At rate of

Truro, Royal Cornwall Infirmary.—H.S. £170.

Tunbridge Wells and Counties General Hospital.—H.S. £16

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O.

West London Hospital, Hammersmith-road, W.—H.P. and H.S.'s. Each at rate of £100.

Westminster Hospital, Broad Sanctuary, S.W.—H.S. to Eye, Nose and Throat Depts. At rate of £102.

Wolverhampton and Staffordshire Hosp.—H.S. At rate of £

The Chief Inspector of Factories announces vacant appointn for Certifying Factory Surgeons at Langport (Somerset Aspatria (Cumberland).

The Home Secretary gives notice that in consequence o death of Dr. A. Stuart, Medical Referee under the Work Compensation Act for the Central District of the Sheri of Perth, the appointment held by him is vacant. Ap tions for the post should be addressed to the P Secretary, Scottish Office, Whitehall, London, S.W.1 should reach him not later than Sept. 19th, 1928.

Births, Marriages, and Deat

BIRTHS.

BALTER.—On August 14th, at Avenue-road, N.W., the w David N. Balter, M.D., of a son.

HINGSTON.—On August 20th, at Uplands Cottage, Belv drive, Wimbledon Hill, S.W., the wife of Major H. Hin I.M.S., of a son.

RICHARDS.—On August 15th, at Adelaide-road, N.W., the Noel Olivier, wife of W. Arthur Richards, F.R.C.S., daughter.

RUSSELL.—On August 24th, at "Bredon," Alverstoke, H the wife of Dr. Norman L. Russell, of a son.

SKEGGS.—On August 26th, at Bicknor Lodge, Stevenag wife of Dr. B. Lyndon Skeggs, of a son.

SMALLEY.—On August 21st, the wife of Dr. L. Smalley, Mo Cottage, Kenilworth, of a daughter.

TROTTER.—On August 27th, at "Braemar," Haslemere London, N., the wife of Dr. G. Clark Trotter, M Islington, of a daughter.

MARRIAGES.

SHELDRAKE—LANE.—On August 18th, at the Parish C Leamington Spa, William Donbavand Sheldrake, B.S. Lond., to Ida Frederica Lane, youngest daugh the late Mr. and Mrs. W. Billings Lane, of Botti Lincolnshire.

DEATHS.

GREENWAY.—On August 19th, at Alexandra-drive, Sur Charles Melville Greenway, M.R.C.S., L.R.C.P. (l Plumstead), aged 58.

HUGHES.—On August 23rd, at Bristol, following an oper Frank Percival Hughes, M.B., B.S.

KEBBELL.—On August 8th, at a nursing home, Earl's Charles Frederick Vivian Kebbell, M.R.C.S., L.R.C. his 42nd year.

KHAN.—At Gaya, India, on 20th July, 1928, Major Abdus Khan, I.M.S., from heart failure, aged 46. Deeply mo

MCVINE.—On August 16th, at Hazelwood-lane, N., Dr. McVine.

MOORHOUSE.—On August 17th, at Melville-terrace, St Dr. James Ernest Moorhouse, aged 58 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Noti Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HOSPITAL LAW.

LIABILITY OF HOSPITALS AND THEIR PROFESSIONAL STAFFS FOR TORTS.*

By Captain J. E. Stone, *M.C.*, F.S.A.A.,
HON. SECRETARY, INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS.

Operations.

No surgical operation can be performed on an adult ient without his or her consent if it is at all possible to ain it. No operation, therefore, should be performed on atient without the express consent of the patient, or if is not in a position to give such consent, then of his rest relative. Further, an operation must not be carried ther than is warranted by the consent, and this consent uld be founded on full knowledge of the nature and sible extent of the operation and the consequences which may involve. Disregard of these precautions may se the operation to be illegal, and to render the surgeon le to an action for damages. In the case of a child similar cautions should be adopted except that instead of the ient's consent, the consent of a parent or guardian uld be obtained. Even in the case of a child, it may advisable to obtain his or her consent as well, especially he child has attained years of discretion, for the power he parent or guardian over the person of the child does extend to the whole period of minority.

When a person has selected a surgeon to operate upon , and has appointed no other person to represent him ing the period of unconsciousness that constitutes a t of such operation, the law will by implication constitute h surgeon the representative of the patient, and will t upon him the responsibility of so acting in the interests he patient that the latter shall receive the full benefit hat professional judgment to which he is legally entitled. surgeon undertook to perform a radical cure of a left uinal hernia, and to do it gratuitously. When the patient anæsthetised and ready for the operation to commence, ore serious rupture was found to exist on the right side. surgeon accordingly dealt with the right hernia first, nding to deal with the left one afterwards. However, the time the first operation was complete, the patient's dition was not so good and the second operation could be commenced. The patient brought an action for ult and was awarded substantial damages; but a higher rt set aside this decision on appeal. The grounds for were that the use of anæsthesia modified the funda- ital common law rule that consent must be given before operation can be performed. Anæsthesia had post- ed to the period of relaxation and unconsciousness the ing of the complete and final diagnosis of the case, by ch time consent could no longer be asked or obtained. se changed conditions are all for the benefit of the ent, and to allow them to be used as the basis of actions assault or *mala praxis* would be contrary to the public rest. It will be noted that the decision is safeguarded language which makes it safe from abuse, and confers iberty upon the surgeon to carry out a more extensive nore dangerous operation than that for which he has ined consent. A record of all professional staff in ndance at operations should be kept.

Who may Bring Action?

he only person who can properly bring an action for ages done to the person of the patient is the patient self, even though a minor; otherwise in all cases of eons retained by any of the public establishments the ent would be without redress, for it could hardly be ected that the governors of a hospital would bring an on against the surgeon employed by them to attend the l of poor parents who may have suffered from his igence and inattention (Pippin and Sheppard). For- y, when a patient died as a result of the negligent treat- t of a doctor or nurse, any right of action which he at have had in his lifetime ceased on the principle of well-known maxim, *Actio personalis moritur cum persona.* the Fatal Accidents Act, 1846, more commonly known "Lord Campbell's Act," and called "an Act for com- ating the families of persons killed by accidents," it enacted that whenever the death of a person shall be ed by wrongful act, neglect or default, such as would eath had not ensued) have entitled the party injured to maintain an action and recover damages, then the person who would have been liable if death had not ensued shall be liable to an action for damages, notwithstanding the death of the person injured, and although the death shall have been caused under such circumstances as amount in law to felony. Such actions must be for the benefit of the wife, husband, parent, or child of the deceased; be brought by his personal representative, and be commenced within 12 calendar months after the death of the deceased. If there is no legal representative, all or any of the persons for whose benefit such action would have been brought may themselves bring the action.

Rights and Obligations of Patients.

Voluntary hospitals are under no legal obligations to admit as patients persons who come to them for treatment. The fact that an institution is charitable is not in itself sufficient to entitle the public at large to demand free treatment, and cases can therefore be refused without any reasons being given. This right to refuse admission is, however, seldom exercised without some adequate ground for refusal, but such refusal would give the rejected applicant no cause of action against the governing body or the admitting officer.

A patient on admission to hospital submits himself to carry out any rules and regulations prescribed by the hospital with a view to enforcing on the part of the patients decent and orderly behaviour and obedience to orders. All hospitals have such rules, and the retention of a patient is conditional upon his observing such of the rules of the hospital as relate to his own conduct. A patient is entitled to expect to be treated with reasonable care and skill; this care, however, is so much and no more than a patient in that hospital would, according to its rules and practice, in the ordinary course receive. For instance, patients cannot complain at being attended by junior medical officers in the intervals of the visits of the physicians and surgeons, or because matters not requiring the personal attention of a qualified practitioner are left to the sister or nurse of the ward, or if in accordance with the ordinary practice of the hospital students or others accompany the physicians on their rounds. A patient so long as he remains in the hospital is bound to submit to the treatment bona fide ordered by the physician, and to its administration at the hands of the nurses or other agents employed by the hospital to carry out the treatment prescribed. A patient cannot be detained or treated against his will. If he does not comply with the rules of the hospital the proper remedy is not compulsion but expulsion. If it is found necessary to use force to a patient who exhibits violence or is insubordinate, the force employed should be reasonable and never be greater than is absolutely necessary.

Summary of Hospital's Position.

A hospital is *not liable* for:—

(*a*) The negligence of surgeons, physicians, nurses, or other officers in the exercise of their professional duties, provided it is shown that in the selection and appointment of such officers due and reasonable care was exercised. This as a practical proposition exonerates hospitals in most suits by patients, for in the ordinary case hospitals do exercise such care. (The exemption from liability does not follow the hospital because it is a charitable institution.)

(*b*) The negligence of a nurse (or other officer) assisting at an operation or in the carrying out of her purely professional duties.

A hospital *is liable* for the negligence of:—

(*a*) Nurses in the course of purely administrative duties over which the board has control.

(*b*) Other officers while under the control of the board.

(*c*) Its professional staff (surgeons, physicians, &c.) in the course of their professional duties, if it has not exercised due and reasonable care in their selection and appointment.

The mere fact that the officers are or are not remunerated is immaterial. The board are under no greater liability to a paying patient than to a non-paying patient.

Liability to Persons other than Patients.

Hospitals are liable for the negligent injury of those who do not bear to the hospital the relationship of patient—that is, those who are not beneficiaries of the hospital and its charitable purpose. In such suits hospitals are held by the law, as are all other concerns and individuals, to the use of due care—that is, such care as a prudent person would under like circumstances exercise, and failing in that would be liable in such damages as would fairly compensate the injured person. While, therefore, hospitals are held by the weight of judicial opinion to be exempt from liability for injuries to the recipients of their charity if they have selected their staffs with due care, no such exemption applies to injuries to others. Even though it has been proved that

* Two previous articles on this subject were published in THE LANCET of April 28th, p. 895, and July 14th, p. 102.

there was due care in the selection of the agents or servants where the relation of patient does not exist, and when the hospital would otherwise be liable, there is no exemption to the hospitals. Hospitals are bound to use ordinary care to have their premises in a reasonably safe condition. Cases coming under this heading would include injuries due to (1) defective lifts, (2) a lift shaft negligently left unprotected, (3) collision with hospital ambulance, (4) defective stairs, (5) falling roof slates or tiles, &c. The absence of reasonable care must, of course, be proved.

This phase of a hospital's liability is not confined to what may be termed strangers—i.e., persons other than patients—but it also includes the employees of the hospital. For instance, injuries suffered by a laundry worker, if not properly instructed in operating the machinery which it was her duty to work, or if caused by insufficient protection or defective condition of the machinery, would give good grounds for maintaining an action against the hospital. The fact that employees receive no money for their services, but only lodging, board, and uniforms, does not defeat their right to bring an action. Nearly all hospitals contract out in respect of their liabilities falling under both the above headings; one or two undertake their own risks by the establishment of insurance funds, into which annual premiums are paid and out of which all accident claims are met.

St. Thomas's Hospital, London, S.E.

"THE WELL OF LONELINSES,"

THE fact that "The Picture of Dorian Gray" is now available in cheap editions, while "The Well of Loneliness" has been withdrawn by Messrs. Jonathan Cape at the request of the Home Secretary, suggests that Miss Radcliffe Hall's book may at some future date be restored to circulation. It is not, of course, comparable in artistic merit with Wilde's work, nor even with Miss Radcliffe Hall's previous novel, but it is an honest attempt to portray the temptations, the emotional conflicts, and the social dilemmas of the homosexual woman. The author has considerable dramatic skill, though her emphasis is sometimes misplaced. The implication that the parents' desire to produce a son may alter the emotional affinities of the daughter born to them is difficult to accept; the origin of abnormal sex attractions cannot be so simply explained. The fallacy of the book lies in the failure to recognise that strong attachments between members of the same sex occur as a phase of normal development. Those who fail to outgrow this phase can be helped to divert their emotions into other channels. If their efforts are ineffectual their life must always be unhappy, for the race is bound to erect such barriers as will discourage the development of affinities dangerous to its existence. This duty is well recognised by Miss Radcliffe Hall. Her book, to which Mr. Havelock Ellis contributes a preface, is certainly not effective as a presentation of the case for social toleration of an abnormal habit of life, nor is there any evidence that the author holds a brief to this end.

JUNGLE AND MALARIA.

THE idea is widespread in the Federated Malay States that jungle causes malaria and that therefore ravines should be cleared of jungle and secondary growth. The Malaria Advisory Board states, however, in its report for 1927, that this is by no means always true, and many instances are known in which severe outbreaks of malaria have been caused by clearing jungle. An emphatic warning has therefore been issued against indiscriminate felling of jungle, and the attention of the public is invited to the following points: (1) If the health of those living close to a jungle-covered ravine is good, on no account do any clearing. (2) If the health is not good, owing to attacks of malaria, search thoroughly for other possible sources of mosquitoes before blaming the jungle. (3) Do not clear a ravine, unless you are prepared to drain and oil it thoroughly. (4) Sometimes jungle is dangerous, but before felling it you should seek the advice of your medical practitioner. The Health Department will be glad to coöperate with him in this important matter.

The Health Department of the F.M.S. states its willingness to coöperate with the local practitioner in coming to a decision.

REPORT OF THE IMPERIAL SOCIAL HYGIENE CONGRESS.

WE have received from the British Social Hygiene Council a copy of the proceedings of the Imperial Social Hygiene Congress held at Caxton Hall from Oct. 3rd to 7th, 1927. The Congress was reported at some length in our columns at the time (see THE LANCET, 1927, ii., 782, 829); and Mr. Neville Chamberlain in a preface expresses a hope that the record will have a wide circulation amongst those who are working to raise the moral and social standards throughout the Empire. The report deals in succession with the imperial, medical, and administrative aspects of social hygiene; a full index makes it possible to rapidly to work recorded in any part of the Empire. report can be obtained from the Council at Carteret H Carteret-street, London, S.W. 1.

NEW PREPARATIONS.

Atophan Balsam (Messrs. Schering, Ltd., 3, Llo avenue, London, E.C. 3. Manufacturers: Schering-K baum A.G. Berlin, N.39).—The use of atophan in facilit the elimination of uric acid in gout and rheumatic affect as well as its value in neuralgia and sciatica, are well kn It is now made in the form of a balsam, being an associ of atophan-amylester 10 per cent., phenyl salicylate 1 cent., and camphor 5 per cent., with a fatty soap The balsam can be used externally either per se or supplement to internal treatment by atophan. Experin have shown that the preparation has high absor qualities, confirmation being given here by the excreti the components into the urine. The use of the prepar is particularly indicated where local and massage treat are required simultaneously. It is put up in collap tubes. About ½ oz. per day is recommended for use, the tubes contain about 1¼ oz.

Zymocide (Messrs. Reed and Carnrick, Jersey City, Agents: Messrs. Coates and Cooper, 41, Great Tower-st London, E.C. 3).—This is described as an antiseptic sisting of eucalyptol, thymol, menthol, methyl salic boric, and benzoic acids with other aromatic ingred and alcohol 20 per cent. by volume. It is non-irritatin non-poisonous, and is intended for use as a general antis where it already enjoys popularity as a vaginal douch a mouth wash. A 25 per cent. solution has been empl for cleansing the eyes following traumatism, and ir treatment of conjunctivitis, blepharitis, catarrh of lacrymal passages and other ocular inflammations. put up in bottles containing 14 fluid ounces.

Robinson's "Patent" Barley in Powder.—Messrs. R Robinson and Co., Ltd., Carrow Works, Norwich, sent us a specimen of their well-known product, used food for infants and for making potable barley wate barley puddings. As a result of suggestions and criti from medical men they have now fixed on the tin, in add to the directions, a table of food recipes specially des for infants. The table gives in parallel columns the a the infant for the first four weeks, and thereafter fo first nine months of its life, and the weight in pounds is recognised as agreeing satisfactorily. Further col give the quantity of the suggested foods and the numb feeds per day in accordance with the age and weigh note on this table of recipes pointing out that infants sh preferably be fed by weight rather than by age gives a which might far more frequently be acted upon by public—viz., that where the weight of an infant doe clearly correspond with the age the medical man shou consulted.

THE BUCKSTON-BROWNE PRIZE.

A CORRESPONDENT asks for details in regard to the Buck Browne prize to which he has found a reference in columns. The prize was founded by Mr. Buckston-Bro to whom the medical profession is indebted for his gene in many directions, in memory of a son who lost his l the war. The interest on a sum of money given fo purpose provides a cheque for £100 and a medal whic given for the best essay on some subject selected b Council of the Harveian Society. The prize is aw every two years, the first award having been made in to the late Mr. Lionel R. Fifield for his essay on new gr of the urinary bladder. An amplification of that exc essay was reviewed in THE LANCET recently.

A BROCHURE ON TEA.

WE have received from the Mazawattee Tea Com Ltd., an illustrated booklet setting out the connexi the company with the history of tea in an interesting ma Figures are given to show the vast increase in import of tea which has been accompanied by the dramatic f prices, the figures really forming a commentary social developments in the United Kingdom during 250 years. The Mazawattee Tea Company in their pam point out that they were the first firm to bring home t public that, as dealt with by experts in the fine a blending, teas grown within the British Empire present all the qualities which made those of China po We do not suppose that anyone who is a real amate China tea would suggest that the blends have all the qua which personally appeal, but the blends are held on ground to have other qualities which form satisfa compensation; anyhow, those of this firm have e their wide reputation.

THE address of the Deutsche Medizinische Wochens is now Berlin W. 30, Viktoria Luise Platz 1.

Ingleby Lectures

ON

SOME RECENT ADVANCES IN OUR KNOWLEDGE OF

CKETS AND ALLIED DISEASES.

Delivered at the University of Birmingham

BY LEONARD G. PARSONS, M.D., F.R.C.P. LOND.,

YSICIAN TO THE CHILDREN'S AND GENERAL HOSPITALS, BIRMINGHAM.

LECTURE II.*

CORDING to most authorities the primary defect ncomplicated human rickets is an impaired rption of phosphorus from the bowel. Findlay the Glasgow School do not accept this view regard defective calcium absorption as the tial factor. To determine which view is the ct one is, however, a matter of extreme diffi-, because the relationship between these two ents in all phases of their metabolism is so ate and reciprocal (Murdoch).

ORS INFLUENCING THE ABSORPTION OF CALCIUM AND PHOSPHORUS FROM THE BOWEL.

cessive amounts of calcium in the diet tend to ase its absorption and retention but to impair phorus retention with the result that consider- amounts of phosphorus are diverted from the to the stools. Conversely, if the phosphorus e diet is excessive, calcium metabolism is un- urably influenced, there is an increase of calcium e fæces, and its excretion in the urine becomes less. retention of one element in the intestine by an ssive amount of the other is best explained by formation of insoluble calcium phosphate. To in the maximum absorption of both elements liet should, therefore, contain amounts of calcium phosphorus sufficient in quality and properly nced, the percentage of calcium being greater that of phosphorus. Both these requirements net if children take one pint of milk daily.

nother important factor in the absorption of um is the presence of certain fats in the dietary their normal absorption from the intestine. nts with a normal fat absorption must take 2 to 6 g. of butter fat per kilo of body-weight nsure the absorption of 0·1 g. of calcium oxide kilo of body-weight. A child fed on a low fat ary may, indeed, show a negative calcium balance. infant whose diet, a milk mixture containing r cent. of fat, contained 0·44 g. of calcium oxide day, showed a percentage absorption of 34; eas when fed for 17 days on a mixture containing per cent. of fat, it showed a negative calcium nce, although the calcium intake was more than e as much as on the previous diet (due to the tion of calcium caseinate). The presence of amounts of unabsorbed fat in the intestine also lead to a negative balance; thus a negative w calcium retention is often found in cœliac ase. Again, in infantile biliary cirrhosis, owing e exclusion of bile from the intestine, fat absorp- is very defective. In one case of this disorder gative calcium balance and in another a low tion was found. (See Table I.)

lfer has produced evidence showing that the rption of calcium only occurs in the upper part e intestinal tract. The solution of the calcium in the food is effected by the acid of the gastric , and absorption proceeds until the acid mixture me and phosphoric acid is rendered alkaline by intestinal secretions, when calcium phosphate is ipitated in insoluble form. It has, therefore, been suggested that an increased acidity in the upper part of the intestinal canal would increase the absorption of calcium. Bergeim maintains that acidity, and especially lactic acid fermentation, increases absorption of calcium, and has shown that lactose largely promotes its absorption, whereas maltose and glucose do so to a much lesser degree if at all. Breast milk contains much less calcium than cow's milk, but it is almost completely absorbed; this, he believes, is the result of a high proportion of lactose and of the acid intestinal reaction in breast-fed infants. My own observations lead me to believe that an increased acidity alone does not necessarily cause increased calcium—although it does produce increased phosphorus—absorption. Thus in the cases of biliary cirrhosis, to which I have referred, large amounts of fatty acid were present in the intestine, yet calcium absorption was very poor, and in one case there was a negative balance.

TABLE I.—*Infantile Atrophy.**

—	Calcium.		Phosphorus.	
	Intake.	Percentage absorbed.	Intake.	Percentage absorbed.
Cow's milk ..	1·04 (31 cases)	45·6	—	—
Lactic acid milk	1·32 (14 cases)	35·4	0·76 (11 cases)	71·3
HCl milk	1·22 (6 cases)	51·6	0·62 (1 case)	85·3
Almata	0·92 (6 cases)	72·5	0·63 (1 case)	46·5
Biliary cirrhosis.				
Cow's milk (M. C.)	0·98	0	1·07	92·1
	1·44	0	1·32	85·7
Lactic acid milk (A. J.)	1·35	13·9	0·66	94·9

* The figures given represent the amounts taken in grammes in 24 hours.

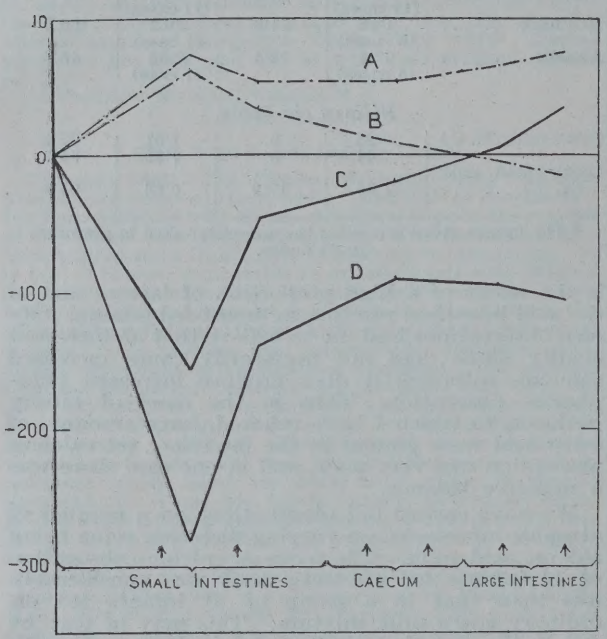
We have carried out observations on a number of atrophic infants fed on varying dietaries, some being fed on acid milk. The average calcium absorption of 14 infants fed on lactic milk was considerably less than that in a group of 31 infants fed on ordinary cow's milk mixture. This may in part be due to the fact that children fed on lactic acid milk excrete more fat than those fed on ordinary milk mixtures. Four children fed on hydrochloric acid milk (prepared by adding one ounce of decinormal hydrochloric acid to four ounces of milk), however, showed a higher absorption of calcium, and although there was a marked increase in the amount of calcium excreted in the urine, the actual calcium retention was definitely higher than in children fed on cow's milk. Finally, a group of six infants fed on Almata, a food which has a buffer value similar to that of breast milk, showed the highest calcium absorption of all the children examined. Increased phosphorus absorption, as the result of increased intestinal acidity from excess of fatty derivatives in the intestine, is to be explained by the formation of large amounts of insoluble calcium soaps so that less calcium is available to bind phosphorus and the latter can be absorbed. (See Table I.)

The absorption of calcium and phosphorus from the bowel can be increased by the oral administration of cod-liver oil, ostelin, irradiated ergosterol, or by exposing the skin to the sun's rays, or by artificial ultra-violet irradiation. Moreover, rats fed on a high-calcium, low-phosphorus, rickets-producing dietary develop a marked alkalinity of the fæces which can be reduced to the acid side of neutrality by any of those methods. Again, the child fed on a low fat dietary, having a low or negative calcium retention, can be made by such methods to absorb calcium well; and in cœliac disease the same results are obtained by irradiation or the administration of irradiated ergosterol in solid form. From all of these considerations it would appear that it is not intestinal

* Lecture I. appeared in THE LANCET of Sept. 1st.

acidity *per se* that is so important in absorption, but the presence of some factor (vitamin D), which directly increases absorption and also produces an acidity, and that the reason why some fats, such as cod-liver oil, are necessary for proper absorption of calcium and phosphorus is that they contain this vitamin.

New light has been shed on the question of calcium and phosphorus absorption by work carried out by Bergeim. Albino rats were fed for 25 days on a high-calcium, low-phosphorus dietary and rickets was produced. They were then divided into two groups; to one group were given ten drops of cod-liver oil daily for five days, to the other, ten drops of olive oil. The animals were then killed and estimations made of calcium and phosphorus in the small intestine, cæcum, and large intestine; the results are seen in the diagram. Both groups of



Average absorption of calcium and phosphorus from intestines of rachitic animals and animals given cod-liver oil. A, cod-liver oil: calcium. B, rickets: calcium. C, cod-liver oil: phosphorus. D, rickets: phosphorus.

animals showed considerable calcium absorption in the small intestine. On this diet, which produces a low phosphorus rickets (the analogue of human rickets), the rachitic condition could not therefore be due to a failure of calcium absorption. In the same area both groups also showed considerable excretion of phosphate—i.e., excretion of phosphate appeared to be an important factor in promoting calcium absorption. In the lower bowel, in the animals receiving cod-liver oil, there was an approximate balance between excretion and absorption of calcium and a high calcium balance resulted. Phosphorus was also reabsorbed so as to bring about a positive balance. In the other group calcium excretion was more marked than absorption, leading to a negative balance; also there was a failure of phosphate to be adequately reabsorbed so as to produce a positive balance. The re-excretion of absorbed calcium into the lower bowel, so that a negative balance results, must be due to the failure of the bones to fix calcium. This failure, as pointed out in the first lecture, is not due to defects in the bone cells but to low blood phosphate, which, in Bergeim's view, is the result of the inability of the tissues of the body to maintain the proper concentration of blood phosphate by breaking down the organic phosphates which they contain. Antirachitic vitamin, he believes, facilitates this action and therefore elevates blood phosphate, and the absorbed calcium is deposited in the bones. The absorbed cal is hence not re-excreted in the lower bowel, phos absorption is unhindered, and the phosphate ba becomes positive. I am not convinced that Berg explanation is correct in all its details, althoug results appear to be incontrovertible. A refe to the diagram shows that, although it would a as if excretion of phosphate favoured calcium ab tion, yet in those animals receiving cod-liver o calcium absorption in the small intestine was h with a smaller excretion of phosphate. Furthe states that in three non-rachitic rats which wer on a milk diet which was high in calcium and phorus "an acid condition generally prev throughout the intestines, due presumably to acid fermentation, and both calcium and phosp were absorbed to a considerable extent in the intestines." Also, if phosphate excretion fa calcium absorption, it is not clear how calcium e tion hinders phosphorus absorption. Indeed, i arguments are correct the reverse process v appear the more logical. It is, I think, much probable that the antirachitic vitamin exert effect by an alteration of the pH of the inte canal rather than by any action such as Be suggests. Reference has already been made t influence of acidity of the intestinal canal o absorption of calcium and phosphorus and t fact that this acidity is largely due to the pre of the antirachitic factor. Recently Red Willimot, and Wokes have estimated the p contents of various sections of the gut of ro by a method similar to that of Bergeim, an curves they obtained on a low fat rachitogenic show that the fæcal alkalinity corresponds well Bergeim's curve of calcium absorption. Admin tion of cod-liver oil or irradiated cholesterol to animals restored the acidity of their intestinal tr

From this review it will be seen that it is a impossible to say which of the two, calcium or phorus absorption, is actually at fault; pro both are, but perhaps on the whole the evi favours the view that defective absorption of phorus is the more important.

TETANY.

Infantile tetany is very closely associated an quently occurs with rickets, in fact, some autho regard it as a nervous manifestation of rickets. cases of infantile tetany the serum calcium is The blood phosphorus may also be low, inde always is so if there are manifest symptoms of ri but the presence of low serum calcium is path monic of infantile tetany and is the one characte sign of the disease. In manifest tetany the ca may fall as low as 6 mg. per cent., and in latent t it is usually about 8 mg. per cent. Now ca exists in the blood in both ionised and un-io forms. The un-ionised form is in part inor as bicarbonate and acid phosphate. Cameron Moorhouse have suggested that the calcium co of the cerebro-spinal fluid, normally 5·3 mg. per may be regarded as the amount of diffusible ca —i.e. the inorganic and ionic calcium. In inf tetany the calcium in the cerebro-spinal fluid is gr reduced and may be entirely absent. From results of experiments on the filterability of the calcium through collodion membranes under a tive pressure, and by means of the Rona-Taka equation, the amount of calcium present as in the blood in small children has been estimat be 2·1 to 3·4 mg. per cent. with an average of 2·6 All the methods of directly determining the an of ionic calcium are open to considerable critic this is unfortunate, because the work of Loeb others has shown that the excitability of the n muscular mechanism depends on the relative centration of the calcium, magnesium, sodium potassium ions, according to the formula: $\frac{Na}{Ca}$ In infantile tetany potassium, magnesium, and so in the serum are all normal, and it is, therefor

calcium which is the determining factor in the t of the disorder.

tany, of the same nature as infantile tetany, occurs in cœliac disease. It may, however, ar without any diminution in blood calcium, as, nstance, in gastric tetany, a condition which may lop when there is continuous vomiting of acid ic contents. This sometimes happens in pyloric sis of infants and is the explanation of the con- ons which occur in that disease, and which times prove fatal. Examination of the blood ich cases reveals that there is a shift of the pH he alkaline side—i.e., an alkalosis—as a result hich less calcium is ionised and tetany results.

uring digestion the blood normally yields acid equiva- especially HCl for the secretion of hydrochloric acid, an excess of basic equivalents is formed. These are diately neutralised by the carbon dioxide of the blood, esult being an increase in the BH CO_3 of the blood. BH CO_3 content again falls, however, one to one and a ours after the meal, as HCl is reabsorbed and replaces CO_3." (Drucker.)

e loss of hydrochloric acid by vomiting and the of reabsorption in pyloric stenosis produces an osis. The occurrence of tetany after large doses carbonate of soda is also due to alkalosis, as is form known as superventilation tetany, which ought about by forced respiration and in which blood calcium is normal. This is undoubtedly ause of the convulsions which are occasionally after rapid respirations in children suffering post-encephalitic respiratory tic. (See Table II.)

e threshold mechanism of blood calcium (of g. per cent.) appears to be a very delicate one. calcium content can be raised above normal travenous injection of calcium salts, but the s a fleeting one and the extra calcium is soon cted into the alimentary canal and the normal ed. Recently Collip has shown that the para- id glands contain a hormone which raises the calcium. Injection of large doses may produce calcæmia and death, but even using this hormone necessary to repeat the injection frequently to ain the blood calcium above threshold value. tany, as we have seen, blood calcium is diminished, he parathyroid hormone raises it to normal and tetany, although only for a short time unless ose is repeated. It is possible, in animals from the parathyroids have been removed so that a has been produced, not only to cure tetany eans of the hormone but also to produce hyper- mia and death. The parathyroid hormone, er, does not increase the absorption of calcium the bowel, but actually mobilises the fixed m from the bones and other reservoirs, and faction appears to be to maintain the calcium blood at the normal level and to balance the ution of calcium between the tissues and the It is, therefore, useless in the treatment of unless means are also taken to increase calcium tion from the bowel.

must envisage rickets as usually primarily a onal disorder of the intestinal tract whereby n or phosphorus, or both, are not properly ed, either because there is an inefficient supply se elements or because of the absence of vitamin ince this vitamin can act whether supplied the skin by inunction or when taken by the mouth, it seems probable that it acts after absorption from the intestines and not, as suggested by some authorities, by a local action on the intestinal mucous membrane. The injection of cod-liver oil subcutaneously has been stated to have little or no effect on rickets, probably owing to the difficulty in dealing with fat that has not been through the processes of digestion. The antirachitic factor in cod-liver oil has been found to be contained in the unsaponifiable fraction of the oil, and by injecting intramuscularly a concentrate of this active fraction, Wilkins and Kramer produced a cure in two cases of active rickets. This is strong, although not conclusive, evidence that the antirachitic effect of the oral administration of cod-liver oil occurs as a result of absorption of the oil. The absorption of fats containing vitamin D should therefore be essential for the prevention of rickets, or, conversely, a child who is taking a fat-free diet, or who is not absorbing fat properly, should develop rickets. I have already mentioned the effect on the calcium balance of a diet of skimmed milk, and of the presence of large quantities of unabsorbed fat in the intestines, and also the occurrence of xerophthalmia in babies fed on a skim milk dietary.

There are certain conditions in childhood associated with defective fat absorption, of which the most important are severe and lasting jaundice, such as occurs with congenital obliteration of the bile ducts and some forms of cirrhosis of the liver; diarrhœa; cœliac disease. I have never seen xerophthalmia in any of these conditions, but Bloch and Wagner have described its occurrence in association with severe and lasting jaundice. The amount of unabsorbed fat in those forms of icterus is very great, yet, in spite of the fact that these infants have a low or negative calcium balance, they do not develop rickets. The probable explanation of this apparent anomaly is that growth in such conditions is practically inhibited, and in infants where there is no growth, there is no rickets. That these children may, however, develop rickets when growth starts is well illustrated by a case recorded by Bloch.

CŒLIAC RICKETS.

In cœliac disease of long standing all grades of severity of rickets are met with, and here again growth is, I believe, the activating cause. The bone is osteoporotic before any considerable degree of growth occurs, although rickets rarely develops before the age of 7. The child suffering from cœliac disease passes copious stools containing large amounts of undigested fat, for the treatment of which it is necessary to give a low fat dietary and therein lies the reason for the onset of cœliac rickets. Whilst this is correct, the amount of fat absorbed in cœliac disease on a full fat diet is often considerably higher than would be expected on clinical grounds, and very much greater than occurs in chronic jaundice; indeed, on a low fat dietary, such as skimmed protein milk, the absorption may reach the high figure of 94 per cent. Even with the deliberate addition of fat to the diet for short periods, although the amount present in the stool is increased, yet the amount absorbed is considerable and indeed, within limits, the higher the fat intake the greater the amount of fat is absorbed. Any attempt to prevent the onset of rickets by giving cod-liver oil, however, is unsuccessful because, as with any other extra fat, if continued for more than a short period, an increase in the diarrhœa, the size, offensiveness, and fat content of the stool is produced, and the child goes downhill. On the other hand, a low fat dietary improves the clinical condition and as a result growth may occur and rickets develop. Examination of the blood in cœliac rickets usually shows low serum phosphorus and calcium, and the condition can be cured by administration of dry irradiated ergosterol, or cholesterol, or by exposure to the ultra-violet rays. All this is evidence that the disease is due to fat-soluble vitamin deficiency, yet in spite of this xerophthalmia has so far not been reported, although growth is severely stunted. We have, therefore,

in cœliac disease the converse of the condition described by Bloch in infants fed on a skimmed milk dietary. In cœliac disease there is rickets but no xerophthalmia; in dystrophia alipogenetica there is xerophthalmia but no rickets. The explanation of this anomaly seems to be that after the period of infancy the child is more susceptible to a diminution in the supply of D- than of A-vitamin. Rickets occurs in cœliac disease only when the latter is severe and of long standing. It seems that, although as a result of defective fat absorption, normal amounts of vitamin D are not absorbed, yet enough is absorbed to enable the child to obtain sufficient calcium and phosphorus to ossify a fragile osteoporotic bone during the period whilst growth is slow, but that this subnormal absorption of vitamin D is quite insufficient to ossify growing bone, and so rickets results. A low fat dietary seems to ensure a better percentage absorption of fat, and, therefore, probably ensures the absorption of any fat-soluble vitamin that may be present in the diet, but here again the amount of vitamin D is so small as to be totally inadequate when growth occurs. From what has been said it is obvious that I regard the osteoporotic bone as a prerachitic stage, only awaiting a period of growth actually to declare itself as frank rickets.

It is not very unusual to meet with cases of rickets which appear to resist treatment by cod-liver oil but which respond to treatment by light or by the administration of ergosterol. One such case was reported to have been under treatment with cod-liver oil for years, but at the age of 7 was unable to walk because of severe and progressive rickets. Radiograms showed an extreme degree of osteoporosis and a large rachitic metaphysis. Treatment by light and ergosterol has, however, completely healed the bones, and the child is now able to walk. In another case, in spite of a life spent under ideal conditions, most careful dieting and the administration of cod-liver oil, a girl presented, when 3 years old, evidence of rickets of moderate degree, which has increased slowly until her present age of 8 years. There was a history of mild digestive disturbances, and examination of her stools showed a higher fat content than usual, and therein, in my opinion, lies the cause of her rickets, which I believe can be cured by light and ergosterol. Both these children were smaller than normal children of the same age, and although they could not be classed as cases of cœliac disease they are, in my opinion, examples of a subnormal absorption of fat—particularly the fat-soluble vitamin D—extending over a long period of time. Cases of cœliac rickets and those to which I have just referred require treatment for much longer periods than ordinary rickets in order to effect complete cure.

Diarrhœa, another cause of defective fat absorption in childhood, is of little importance in producing rickets because, unless the condition is one of cœliac disease, it is usually only transitory and, indeed, leads to starvation which produces arrest of growth and therefore absence of rickets.

Rickets Occurring as a Result of Defective Excretion

As already pointed out, there does not appear to be any bone disorder associated with defective calcium excretion, but a very different state of affairs exists with defective excretion of phosphate. The latter occurs in chronic interstitial nephritis, a disease which in children produces marked infantilism and not infrequently severe bone deformities ranging from a mild degree of genu valgum to the severest manifestations of rickets—"renal rickets." In these children the defect does not lie in the intake of calcium and phosphorus, nor is it due to the absence of vitamin D, or sunshine, but is purely a defective excretion of phosphate by the kidneys. Examination of the blood reveals nitrogen and phosphate retention, an acidosis, and frequently a high degree of lipæmia. The phosphorus values are often even higher than would appear at first sight, because, although 5 mg. per cent. is the normal concent in infants, many of these children have reach age when the normal blood phosphorus is consid below that figure. Blood calcium in comparis blood phosphorus is always low but in actual va frequently at or above the normal figure of 10–1 per cent., a very different state of affairs that found in azotæmic nephritis of adults and the injection of phosphate into animals or chi

In azotæmic nephritis of adults the highe retention of phosphorus the lower is the calci the serum. Injection of phosphate into anim children raises blood phosphorus, lowers blood ca and in some cases produces tetany. Why, the does not blood calcium become low and tetany in renal rickets? I think the answer may be the increased blood calcium is an effort on the of the child to prevent tetany. Tetany is a s disease, and to prevent it I suggest that the mobilises calcium from the bones, producing porosis and rickets, an action similar to that duced by the injection of parathyroid hormon that suggestion is true, administration of the ho should definitely make renal rickets worse. I case the bone condition was reported by my logist colleague (Dr. Teall) to be worse after ad tration of the hormone, but the variations in the of the rickets are so marked in the ordinary c course of renal rickets that too much impo cannot be attached to this observation. T does not occur in chronic azotæmic nephri adults in spite of the fact that the blood calci diminished; the explanation usually accept that advanced by de Wesselow, that in this of nephritis there is an acidosis and usually a di tion of the bicarbonate content of the plasma, conditions favour an increased ionisation of ca There is, however, another factor of importa explaining the immunity of the adult from t It has been shown that if the blood plasma i jected to ultra-filtration under negative pressure is a considerable diminution in the calcium c of the filtrate in tetany but not in chronic nep In the latter, therefore, the diminution of ca in the plasma is largely due to diminution in diffusible calcium, or, in other words, is chiefl to diminution in calcium bound to protei renal rickets there is no diminution in the ca of the filtrate. Indeed, as would be expected theory is correct, in some cases there is an inc Occasionally, however, tetany does occur in rickets, but so far I have not been able to inves a case. Acidosis occurs in renal rickets, and no does it increase ionisation of calcium, but it washes out calcium from the calcium reservoir presumably from the bones (Ross and Scriver therefore helps to produce rickets.

There are, therefore, two factors which cont to the causation of osteoporosis and rickets in kidney conditions in childhood: (1) some mecha probably a protective one, which keeps the calcium at a higher level than is usual in an azo nephritis; (2) acidosis.

There is, however, a third and much more i tant factor to be considered—namely, the def excretion of phosphorus. It is possible to see r develop in a case of renal infantilism, heal, and relapse. Thus there is produced a flux be healing and relapse, and this can be correlated periods in which the blood-phosphorus waxes wanes. If estimations of blood-urea or non-p nitrogen are made, it is found that the cur phosphorus retention parallels the curve of nit retention. "Renal" infants pass through attacks of uræmia before the final one closes chequered career. Such attacks, I believe, their rickets worse by increasing the disparity be calcium and phosphorus, whereas in the perio improvement the phosphorus may even retu normal limits, with the result that the cal phosphorus ratio becomes normal and the r heals. Contributory factors in this healing

ıed degree of acidosis, and a lessened depressing
of phosphorus on calcium and of the resulting
to call on the calcium reservoirs.
vould also draw attention to the fact that any-
which increases phosphorus absorption from
limentary tract may make the condition worse.
ıite evidence has, I think, been produced by
and myself showing that ultra-violet irradia-
far from ameliorating, actually increases the
tic manifestations. Let me add in passing that
nal rickets we have another illustration of the
of growth in the development of rickets, because
ıose rare cases which survive until the later
s, when the growth period has ceased and the
ıyses joined up, rickets does not occur, although
ɔone is still osteoporotic to some degree and the
ım phosphorus ratio is abnormal.
ɔm what has been said it will be gathered that
ard renal rickets as belonging, like cœliac rickets,
e low calcium category. The occurrence of renal
ts also proves the importance of the calcium-
phorus ratio, since if the calcium-phosphorus
uct were a correct guide it would put these
mities far outside the rachitic range. It may
be asked, therefore, what is the proof that the
ition is rickets? I think no one will question
act that some of the cases show a radiographic
arance absolutely indistinguishable from rickets
"rachitic type"), but, on the other hand, there
radiographic manifestations which we have
l the "woolly," "honeycomb," or "stippled
" which are totally unlike that seen in ordinary
ts. There is another type, which we have called
'atrophic type," which resembles cœliac rickets,
although I have never seen the rachitic change
the atrophic type I think they can do so, just
times we see in uncomplicated rickets a radio-
al picture absolutely identical with the atrophic
and with cœliac rickets. In the "woolly,
led, or honeycomb type" osteoporosis is present,
iaphysis is straight but there is a long metaphysis,
it is in the latter that the severe deformities so
ıcteristic of the condition occur. The meta-
is shows irregular ossification, giving the appear-
of honeycombing, stippling, or woolliness, and
r the periosteum the bone may appear to be
d. The changes do not appear to the same
e in all the long bones. As the change advances
bsence of subperiosteal bone becomes so marked
the end of the bone collapses, and since this
ıce of bone is usually more marked on one side
the other the collapse usually occurs sideways,
the result that the most extreme deformities
ɔroduced. The skull in some cases of this type
s most extraordinary changes, marked stippling
present. In the severest case that I have
ved all trace of inner and outer tables of the
al bones had disappeared and the bone was
thickened, the whole presenting an appearance
inguishable from Paget's disease. Post-mortem
ination of the long bones shows that the woolli-
or stippling is due to the presence of islets of
age deep down in the long metaphysis, and that
ppearance of subperiosteal erosion is also due
mossified cartilage. The metaphysis itself,
ugh long, is not broad and splayed out as in
rachitic type. Although this type cannot be
nised radiographically as due to rickets, and
ɔscopical examination shows that the changes
nt differ from those ordinarily seen in rickets,
roliferative cartilage being much more irregular
broken, yet Prof. Haswell Wilson, who has
ined the sections for me, pronounces them as
tely rachitic in nature—a view also held by
ey.

Conclusion.

ıope that in these lectures I have made clear
recent advances in our knowledge have shown
rickets is a disorder of calcium and phosphorus
metabolism, usually the result of defective
ption of these elements from the bowel; further,
this defective absorption is due either to an inefficient supply of these elements, or of some activating body in the tissue fluids; that this body is probably vitamin D, which in its turn is derived from the alimentary canal, or synthesised by the action of ultra-violet rays on sterols in the skin; but that occasionally the faulty metabolism may be entirely endogenous in origin, as occurs in renal rickets; and finally, that growth is an essential for the development of rickets.

Although rickets existed before Glisson's time it certainly increased markedly after his day, and became almost universal in some grades of urban society, especially in districts like our own Black Country and Glasgow. We must, however, remember that except for the empirical discovery of the curative effects of cod-liver oil some hundred years ago, our knowledge of the disease advanced very little until the last few years. Although there are still many gaps in our complete knowledge of the disorder, recent researches have put us in possession of information that should allow us completely to eradicate all ordinary rickets. Already its incidence and severity are declining, and we can look forward with sure and certain hope to the day, perhaps no further distant than the tercentenary of Glisson's work, when rickets will have become one of that small but increasing number of diseases which possess a great interest for the historian but happily present no terrors of ill-health for the patient and no cause for anxiety on the part of the doctor.

BONE FORMATION AND THE OSTEOBLAST.

By H. A. HARRIS, B.Sc. Cardiff, M.B. Lond.,
Assistant Professor of Anatomy, University College, London; Assistant to the Medical Unit, University College Hospital.

"Quid dicam de ossibus? quae subjecta corpori, mirabiles commissuras habent, et ad stabilitatem aptas, et ad artus finiendos accommodatas, et ad motum, et ad omnem corporis actionem." —*Cicero, De Natura Deorum.*

"Scrape a bone, and its vessels bleed; cut or bore a bone, and its granulations sprout up; break a bone, and it will heal; or cut a piece away, and more bone will readily be produced; burn it, and it dies." —*Charles Bell, Anatomy.*

Cicero and Charles Bell have given pithy descriptions of the marvels of bone, the tissue which, in common with bone-marrow, displays the highest powers of regeneration and repair in the whole human economy. Sir Arthur Keith [1] has recently asked "Quid dicam de ossificatione?" The answer to the problem of ossification has not yet been found, and to review the search for the mode of ossification is to review the history of morbid anatomy. No subject has been attacked more vigorously, no subject has been deserted more frequently. When Monro Secundus and William Hewson were pleading a priority suit, in relation to their discoveries in the lymphatic system, with Benjamin Franklin as assessor, Abernethy said: "All our knowledge of the absorbing vessels has been obtained by fragments, and our future acquisitions must be made in the same manner." This is equally true of bone development. Our knowledge of the histological structure of bone is a memorial to three Englishmen: Clopton Havers (1650–1702), John Howship (d. 1841), and William Sharpey (1802–1880), who are familiarised in the canals, lacunæ, and fibres which bear their names. The bone corpuscles were first described by Purkinje and Deutsch in 1834. The specific terms "osteoblast" and "osteoclast" as applied to cells actively engaged in depositing or absorbing bone respectively were introduced by Gegenbaur and Kölliker and came into general use 60 years ago. It is of interest to note that as early as 1689, just after the invention of the Huyghens eye-piece, Gagliardi, a professor of medicine in Rome, had described certain "claviculi" or "small nails," which are identical with the fibres of Sharpey. Moreover, as Sharpey maintains, the ossification in membrane without the intervening

stage of cartilage formation had been described by Nesbitt in 1736. Coincidently with the slow unfolding of the microscopic structure of bone, the experimental method was pursued by Stephen Hales, Nehemiah Grew, John Belchier, and John Hunter in this country, by Duhamel in Paris, and by Haller in Göttingen. Their methods consisted largely of actual measurements of growing bones and of the feeding of madder to experimental animals. Hales and Grew were activated by the search for vegetable processes in the development of the animal world. The madder experiments of Belchier and Hunter have been repeated on innumerable occasions, the most recent being the work of Prof. Brash,[2] of Birmingham, on the growth of the mandible. It is interesting to note how most modern investigators have failed to appreciate Hunter's description of the sites of deposition of the dye. Hunter [3] insisted on the fact that the whole of the bone was stained by madder, and that the depth of the staining was proportional to the rate of deposition and absorption of the earthy salts.

"But in the full-grown state, it would appear from the circumstances of reddening a *whole* bone by feeding the animal with madder, that a bone, although completely formed, yet is changing its earth, and probably every other part. This effect, however, is much slower than in the growing bone. This would show that the madder does not act as a dye upon the earth which is already deposited in the bone, but only upon that matter which is every day deposited; and as there is a great deal more deposited in a young bone than in an old one in a given time, in the same proportion must it dye sooner than an old one. The new matter that is deposited in an old bone is to make up for the waste that is daily going on in it; but in a very old bone the waste is more than the repair."

This is the first clear expression of the fact that the calcium of the bones is not permanently fixed as a deposit account but can be brought into the circulation as a current account. The recent brilliant work of Collip [4] with parathyroid extract indicates the ease with which the extract can raise the blood calcium to abnormally high values by calling upon the calcium in the bones and muscles.

Grew, Duhamel, and the other botanists regarded bone as the product of the deeper layers of the periosteum, which they regarded as a "cambium" layer, by analogy with the actively proliferating zone of plants. Haller regarded bone as a product of the arteries, which could lay down bone anywhere. Hunter favoured this view, and Sir Arthur Keith [1] has recently attributed to the perithelial cells of the capillaries the power of conversion into osteoblasts. Goodsir, differing from Hunter, believed that the cartilage cells gave rise to "bone-forming corpuscles."

The present-day teaching of the formation of bone in membrane, in cartilage, and in the deep layer of the periosteum represents a consolidation of the views of Sharpey, Kölliker, and Virchow. The source of the osteoblast is, however, still a problem. Stump [5] traces the cartilage cell, the subperiosteal osteoblast, the endochondral osteoblast, the osteoclast, the endothelial cells of the growing capillaries, the primitive blood cells and the "hæmoblasts" to the same young connective tissue cells. This is an extreme statement of the monophyletic origin. Fell,[6] in a study of osteogenesis in the domestic fowl, claims, on the other hand, that the chondroblasts suffer a triple fate. They may give rise to osteoblasts, as described by Ranvier, Retterer, Macewen, and Van der Stricht, or they may give rise to the reticulum of the bone-marrow, or they may degenerate and disappear. Experiments on animals, such as those of Bast, Sullivan, and Geist [7] on the repair of fractured bones, show that the "cambium" layer of the periosteum, the osteogenetic cells lining the Haversian canals, and the cells of the endosteum are all active in the production of new bone. They found that the only site of formation of cartilage in the repair of bones was at the cut edge of the fibrous part of the periosteum. They saw fibrous tissue cells giving rise to cartilage cells. Carey and Zeit,[8] as a result of the study of the ossifying patella in the dog, emphasise the dual origin of the osteoblast depict both osteoblasts arising from the sub thelial mesenchyme cells accompanying the inv blood-vessels, and osteoblasts formed directly the embryonic chondroblasts in the neighbou of the capillaries.

Nerve-supply of Bone.

The problem of the nerve-supply of bone remained in abeyance. The innervation of two tissues of the body which exhibit the gre power of regeneration and repair, bone and its ma still awaits adequate description. Sir G. Thar Quain's Anatomy (tenth edition), mentions the that distinct nerves can be seen entering nutrient foramina of the long bones. D. Goe has studied the influence of the nervous syste bones and joints. She concludes that bone h somatic and a sympathetic innervation by mea medullated and non-medullated nerve-fibres. Nu ous investigators have found that trophic chang bone follow nerve-section, such as loss of size weight, diminution of inorganic material, an growing animals, defective development. Num observations have been recorded upon the infl in bone of nerve lesions and diseases in man. again, especially in leprosy, regressive changes to be the rule. In general, lesions of mixed n produce more bony changes than those of p motor nerves, and irritative lesions of sensory n seem to be the most potent, as in leprosy. Go concludes, on clinical grounds, that there are sp trophic fibres of sympathetic origin passing to b with corresponding spinal centres. A general trolling centre, so it is claimed, is situated in the in the region of the floor of the third ventricle. obvious that there is much room for anato and clinical research in this field, and that the changes of anterior poliomyelitis and tabes do offer abundant material.

Problem of Calcium Metabolism.

The vast literature relating to bone form was admirably summarised by Gideon Wells the Harvey lecture of 1911. Since that date chemistry and the intensive study of the vita have revealed the complexity of the whole pro of calcium metabolism. Wells stated that questions to be answered are:—

1. Why is calcium deposited in the tissues at all?
2. Why is it deposited in some tissues and not in ot
3. How is the calcium carried in the blood?
4. How is it held in the tissues where deposited?
5. Why is the composition of calcified deposits so stant, qualitatively and quantitatively?
6. What are the causes of rickets and osteomalac

These questions still await concise answers. first question involves the whole problem of senes and death. Calcification occurs not only in ce cartilages but also in tumours, such as fibroid granulomata, in the meninges, and in ten ligaments, and arteries. The second question b to mind the fact that the tissues which un calcification in senescence are the tissues v afford examples of vegetative reproduction, wi without mitotic division of nuclei, in relatively b less areas. Cartilage, which most readily unde calcification, is a tissue in which the cells live b imbibition of tissue juice, removed from an a blood-supply. There is undoubtedly a limit t size of the mass of cartilage which any anima grow, just as there is a limit to the size of a granu When the limit of growth is reached certain c cells degenerate and the matrix calcifies or cas Thus in cartilage proliferation, degeneration calcification are closely related to the veget processes of proliferation without specialisati function and without differentiation of struc leading to old age and death of the tissue. O other hand, bone formation is an active pr distinct from calcification. It occurs in the pre of a rich blood-supply and is accompanied by dif tiation of the primitive cells for function, as di

n mere proliferation. In short, bone is a live ue, actively growing or functioning in an area ly endowed with blood. Calcified cartilage is so scent as to be virtually a dead tissue in an area tively poor in blood-supply.

he question of the carriage of calcium in the od has been attacked with great vigour by the nist. Howland, Shipley, and Marriott and mer [11] have stated that bone normally contains lcium phosphate, that different bones of the same vidual have the same inorganic percentage, that ratio of calcium phosphate to calcium carbonate reater in normal than in rachitic bones, and, her, that the bone contains the phosphate and onate of calcium in the same proportion as the m. R. Robison [12] has disagreed with these views has emphasised the significance of the hexose sphoric esters. He states that the osteoblasts the hypertrophic cartilage cells of the growing nal secrete an active phosphatase which, by rolysing the phosphoric esters of the blood, gs about a local increase of the tricalcium phos- te concentration. This concentration exceeds the ubility product of the salt and leads to its deposition he ossifying zone. Howland and his co-workers not favour simple precipitation as the explanation, regard the process as a chemico-physical one, ending on the activity of the living tissue in a lium in which the concentration of calcium and sphate in the serum and tissue juice exceed a ain minimum value. J. B. Collip [4] in Canada, C. P. Stewart and J. H. Percival [13] in this country, e dealt in particular with the changes in serum ium under administration of Collip's parathyroid mone. The diffusible calcium is markedly increased reby. These experiments indicate the ease with ch calcium passes into the blood from bone and er tissues, and this is a brilliant confirmation of nter's precocious statement about the continuous orption and deposition of alkaline earths in old ue as well as in young bone.

Several attempts have been made to imitate in loidal solutions the actual deposition of tricalcium sphate and calcium carbonate. Barillé [14] in nce and J. C. Watt [15] in Canada have come to the clusion that the salts in bone are deposited by activity of the osteoblasts as a secretory phenomenon. Crétin,[16] in particular, has contributed much our knowledge of the staining reaction of bone of the possible conditions of deposition of the ium salts. He regards the actual areas of muscular achment to be of great significance in determining tilage formation and ossification. The sternostoid and trapezius muscles in relation to the vicle and the occipital bone are differentiated ore the cartilage or bone appears. The point cartilage formation and of bone formation is ays related to the muscular attachment. The nsportation of phosphorus in combination with ali metals converts the primitive tissue into tilage by producing a modification in the umenoids of the matrix. Whereas cartilage is n in sodium, growth ceases when calcium disturbs equilibrium between phosphate on the one hand sodium and potassium on the other. Calcium bonate is now precipitated, redissolved in the sence of alkalies, and then reprecipitated by sphate in the form of basic phosphate or phosphobonate.

Tissue Culture Experiments.

The results of tissue culture experiments have so far n disappointing. A. Carrel and M. T. Burrows [17] tivated conjugal cartilage as early as 1910, but first detailed experiments were those of Fischer [18] in 1922. He cultivated the cartilage s from the sclera of the chick embryo "in vitro," l found that the cells would not grow in the subnce but would grow on the surface of a clot of sma. In the implant the hyaline substance iefies, the cells migrate, increase in size, and tinue to live. No division of the cells was seen. S. Strangeways [19] succeeded in producing multiplication of the cartilage cells in vitro, with typical mitoses. Policard and Boucharlat [20] implanted periosteum and perichondrium of chicks, but in vitro they gave rise to connective tissue cells without the formation of cartilage or bone. A. O. Wjerinski [21] reports the same results in vitro, though a homoplastic transplant in vivo led to strong mitotic multiplication of the cells of the periosteum and actual conversion into osteoblasts. Thus, so far, osteoblasts have not been grown or propagated in vitro by the technique of tissue culture. This suggests that the osteoblast is a purposively differentiated cell which may easily regress into a fibroblast, but will only redifferentiate in the presence of the blood-borne exudate of a living capillary.

The nerve cell of the young embryo has been grown in tissue culture, but the growth has been localised almost entirely in the axone—i.e., in the part of the cell which was shown capable of growth in the adult by Waller's classical experiments on nerve regeneration. The osteoblast, as Burrows [22] has pointed out for the fully matured lymphocyte, polymorphonuclear leucocyte, and many other mononuclear cells, will not grow in a tissue culture. Neither the nerve cell nor the osteoblast can be propagated. Thus these cells seem to exhibit an extreme degree of differentiation.

R. G. Harrison,[23] in 1914, pointed out that cells will not grow in tissue cultures in clotted plasma unless some form of support is afforded, such as the surface of the cover-glass, the surface of the fluid film, or a framework of spider-web, silk gauze, or cotton-thread. In cultures in which the tissue floats free in a fluid medium no outgrowth occurs and the cell succumbs. This phenomenon whereby a cell in the free rounded stage, devoid of support, is unable to grow was described by Leo Loeb and Fleischer [24] under the name of stereotropism. It involves a most fundamental conception of a skeletal support for the cell, and may account for the failure to grow osteoblasts and fully differentiated blood cells such as lymphocytes. Kidney and liver are grown with ease because of their associated connective tissue stroma. Cartilage cells die when they round up near the epiphysis. Osteoblasts apparently require the support of a connective tissue stroma and the adequate supply of blood-borne substances such as vitamin A and ergusia. Only those animals which have a blood vascular system and a cœlom are able to produce an active osteoblast.

Bone Pathology.

The pathology of bone, like the pathology of the blood-vessels, has been so obscured by diverse classifications and a multitude of strange names that certain simple facts escape observation. Chondrodystrophies, osteochondrites, and osteites have been subdivided without end, and dysostoses, aclasias, and dysclasias have been added thereto. Vrolik's term of "osteogenesis inperfecta" is one of the few safe terms in the pathology of growing bone. H. A. Harris's [25] tentative scheme, as a simple working basis for the analysis of bone growth, serves also as a basis for the interpretation of bone pathology. He states that cartilage grows vegetatively by the imbibition of tissue juice in much the same way as bacteria, yeasts, tumour cells, and granulomata. This vegetative proliferation of the cell is largely under the control of the water-soluble vitamins and of those substances which workers in the realm of tissue culture have designed as "archusia" (M. T. Burrows)[26] or "trephones" (A. Carell).[27] The process of proliferation of the undifferentiated cartilage cell is limited by the size of the mass and by the adequacy of nutrition. When the mass of cartilage reaches a certain limit, as in the case of a granuloma, the cells within the mass become senescent, degenerate, and gradually pass into a resting stage which in many cases leads to death. This process of degeneration is accompanied by calcification of the matrix, and is comparable to the phenomenon of caseation and calcification in a tubercle, gumma, or fibroid, or to hyalinisation and the formation of cell nests in a

carcinoma. Lastly, the propinquity of a rapidly growing capillary system in the bone-marrow brings into the region a new set of factors which lead to tissue differentiation as distinct from cell proliferation. The capillaries of the bone-marrow proceed to remove the dead calcified cartilage as they would proceed to remove any other foreign dead body, such as a caseated granuloma or a ligature. The cells of the calcified cartilage that are not quite dead, but rather in a resting or "spore" stage, respond to the approach of the blood capillaries by active amitotic division to form osteoblasts. Any primitive connective tissue cell in the vicinity of the actively proliferating capillary can give rise to osteoblasts, whether this cell be periosteal, perivascular, or reticular. This process of cell differentiation for function is in part attributable to the arrival in the area, via the blood stream, of fat-soluble blood-borne substances. These fat-soluble, blood-borne substances correspond to the "ergusia" or differentiating, energy-producing substance of Burrows, and to vitamin A proper. The osteoblasts are cells designed for work, not for proliferation, and a failure of ergusia or vitamin A leads to the formation of imperfectly differentiated osteoblasts. The degree of differentiation may be so low that the osteoblast is little more than a fibroblast; it may be more advanced, so that the cells deserve the name of "osteoidoblast," but only in the presence of an adequate supply of the blood-borne vitamin A does one see the fully differentiated osteoblast with deeply staining nucleus and numerous basophilic granules in the cytoplasm. This conception of the vegetative proliferative process in cartilage, in contradistinction to the differentiating and functional process in bone, is not entirely new. Its formulation in terms of archusia and ergusia on the one hand, or in terms of water-soluble and fat-soluble vitamins on the other hand, is but an experimental and clinical statement of a long-established teleological fact. Richard Owen,[28] when Curator of the Royal College of Surgeons of England, said, as far back as 1843:—

> "Organic forms result from the antagonistic working of two principles, of which one brings about a vegetative repetition of structure, while the other, a teleological principle, shapes the living thing to its functions. . . . In every species these two forces are at work, and the extent to which the general polarising or 'vegetative repetition force' is subdued by the teleological is an index of the grade of the species."

Evolution is measured by the extent of the triumph of ergusia and the fat-soluble vitamins over archusia and the water-soluble vitamins.

The term metastatic calcification was applied by Virchow to the occurrence of deposits of calcium salts in abnormal sites. There is hardly a tissue in the body which does not present numerous examples of abnormal calcification, from ganglion cells and skin on the one hand, to kidney, liver, lungs, and gastric mucosa on the other. Most of the cases of calcification occur in an area of senile or necrosed tissue, with a poor blood-supply and a slow lymph stream. There are, however, three marked exceptions, for calcification has been repeatedly reported in the lungs, kidneys, and gastric mucous membrane. These three areas are the sites of excretion or secretion of acid substances, and the tendency to calcification in these areas may be an expression of this fact. Cartilage, when calcifying, stains deeply with basophilic dyes, and has an acid reaction. Wells[29] has stated that the well-known tendency of muscle-fibres to calcify in the vicinity of recent wounds, including laparotomy wounds, may be due to the precipitation of calcium salts by lactic acid, set free by the injury to the muscle-fibres during the process of degeneration. The question whether a site of calcification shall also become a site of bone formation is apparently a question of blood-supply. Tendons, ligaments, the media of arteries and caseating granulomata rarely produce true bone, but muscle, kidney, lung, suprarenal, and tonsil frequently do, by reason of the association of primitive connective tissue cells with a rich capillary network. Cushing and Weed,[30] in their experimental studies on cerebro-spinal fluid of cats, observed numerous instances of calcification and ossification of the arachnoid membrane. Calcification occurred in avascular areas, for the nutrition of the arachnoid is obtained through the cerebro-spinal fluid rather than through the blood stream. On the other hand, every case of true bone formation was vascular and could be attributed to the proliferation of mesothelial cells in a vascularised area, as distinct from the calcification of aged cells in an avascular area. In the aged cadaver of the dissecting-room calcification of the membranes, both dura and arachnoid, is common. True bone formation, on the other hand, is rare.

For a considerable time it was thought that the secret of calcification would be found in the formation of calcium soaps with fatty acids, for the pathologists had described calcification by the formation in degenerating lipomata as early as 1849. The absence of any appreciable amount of calcium soaps from areas of normal calcification has negatived this idea, and the presence of large quantities of calcium soaps in certain stages of the digestion of fat without associated calcification is also against the theory. We seem to be confronted with the need for a new chemical concept. The hydrogen-ion concentration and the salt content must be known not only for the arterial and venous streams but also for the contents of the lymphatics, for the tissue juice, and for the interior of the cell. The varying percentage of calcium which can be absorbed by the cartilage designed for later calcification was shown by Wells.[10] He showed that pieces of epiphyseal cartilage, tracheal cartilage, and costal cartilage absorb decreasing amounts of calcium salts, irrespective of whether the cells in the transplant are alive or dead. Moreover, decalcified bone-grafts are known to be less efficient than normal bone-grafts, so that a preliminary calcification or power of calcium absorption in the tissue seems to be advantageous to subsequent ossification. Pathological ossification, rather than normal ossification, seems to require preliminary calcification of the cartilage or of the necrosed tissue.

Since no chemical ion or soap in cartilage can be proved to be an adequate agent in producing the deposition of calcium phosphate and carbonate, it is interesting to note that Jan Wolf[31] has returned to the problem of chondroitin-sulphuric acid. This substance is a normal constituent of cartilage; it is increased in calcifying cartilage; it occurs in the amyloid deposits of the spleen, liver, and arteries; its calcium salt is very soluble. Jan Wolf has shown that the small veins draining the costal cartilage contain a measurable amount of chondroitin-sulphuric acid, and that this can be stained in situ by mucicarmine or basophilic stains. The acid is not found in the arteries. This suggests that the continuous removal of chondroitin-sulphuric acid from the matrix of the cartilage is necessary to preserve it from calcification. As yet no one has studied the effects on the solubility product of this acid or its calcium salt in the presence of other ions. Even as long ago as 1891, Schmiedeberg[32] suggested that one of the functions of cartilage was the production of chondroitin-sulphuric acid, and that this acid served as a mordant and possibly as a regulator of the processes of nutrition in the tissues. A chemical study of cartilage from this point of view may throw some light upon the metabolism of mucin, which hitherto has been unsolved.

Dentine and the Odontoblast.

Closely associated with the problem of the osteoblast and bone is the problem of the odontoblast and dentine. The metabolic processes involved are closely related, and the pathological processes run parallel in craniotabes, in dysostosis cleidocranialis, in osteomalacia, and in experimental rickets. The problem has been discussed recently by Mellanby,[33] W. Fish,[34] and D. Stewart,[35] and attempts must be drawn to the disturbing evidence adduced by Donaldson and French,[36] who claim that gly-

sts in the molar teeth of the rat after eruption. crown continues to increase in both dimensions; uch as 10 per cent. is added to its length and lth during the first two years, and the growth place in the dentine. This startling observation els us to regard dentine, like bone, as a tissue ct to prolonged growth, peculiarly susceptible anges in the blood calcium, and revealing the processes of absorption and deposition as bone. apid development of caries and the fragmentation e enamel in pregnant and nursing mothers may ue to the inroad made on the calcium of the ne and the resulting shrinkage.

ll more numerous are the problems afforded by arative anatomy, and it is surprising that so has been added to the original observations of Goodsir (1814–1867), who inaugurated the study lcification in sponges and molluscs. Pearl and ice [37] in 1909 performed a classical experiment. anastomosed the gut to the oviduct of the fowl showed that the fæces were covered with a shell. domestic fowl, with its active metabolism and powers of repair, appears to be an ideal animal he study of calcification and ossification. Con- ing the extent to which the costochondral ion and the costal cartilages have figured in the ture of rickets and respiratory diseases, it is nt that a detailed study of the comparative my of these structures offers a promising field esearch. The costal cartilages calcify in old n man, in adolescence in sheep and goats, and become really ossified in birds.

seems that until the chemist explains the colloidal sses which lead to the deposition of the salts lcium in two tissues so fundamentally distinct ying cartilage on the one hand and living bone he other, we must continue to regard the osteo- as a splendid being, endowed with genius, bility, and intelligence, ever ready to perform work at hand.
